**Abstract**

We present a conjecture generalizing the Cauchy formula for Macdonald polynomials. This conjecture encodes the mixed Hodge polynomials of the character varieties of representations of the fundamental group of a Riemann surface of genus $g$ to $\mathrm{GL}_n(\mathbb{C})$ with fixed generic semi-simple conjugacy classes at $k$ punctures. Using the character table of $\mathrm{GL}_n(\mathbb{F}_q)$ we calculate the $E$-polynomial of these character varieties and confirm that it is as predicted by our main conjecture. Then, using the character table of $\mathfrak{gl}_n(\mathbb{F}_q)$, we calculate the $E$-polynomial of certain associated comet-shaped quiver varieties, the additive analogues of our character variety, and find that it is the pure part of our conjectured mixed Hodge polynomial. Finally, we observe that the pure part of our conjectured mixed Hodge polynomial also equals certain multiplicities in the tensor product of irreducible representations of $\mathrm{GL}_n(\mathbb{F}_q)$. This implies a curious connection between the representation theory of $\mathrm{GL}_n(\mathbb{F}_q)$ and Kac-Moody algebras associated with comet-shaped, typically wild, quivers.

# 1 Introduction

Let $\mathbf{x} = \{x_1, x_2, \dots\}$ and $\mathbf{y} = \{y_1, y_2, \dots\}$ be two infinite sets of variables and $\Lambda(\mathbf{x})$ and $\Lambda(\mathbf{y})$ be the corresponding ring of symmetric functions. For a partition $\lambda$ let $\tilde{H}_\lambda(\mathbf{x}; q, t) \in \Lambda(\mathbf{x}) \otimes_{\mathbb{Z}} \mathbb{Q}(q, t)$ be the *Macdonald symmetric function* defined in [10, I.11]. These functions satisfy the Cauchy identity (in a form equivalent to [10, Theorem 2.3])

$$\operatorname{Exp}\left(\frac{m_{(1)}(\mathbf{x})m_{(1)}(\mathbf{y})}{(q-1)(1-t)}\right) = \sum_{\lambda\in\mathcal{P}} \frac{\tilde{H}_\lambda(\mathbf{x}; q, t)\tilde{H}_\lambda(\mathbf{y}; q, t)}{\prod(q^{a+1} - t^l)(q^a - t^{l+1})} \tag{1.1.1}$$

where Exp is the plethystic exponential (see, for example, [17, §2.5]; we recall the formalism of Exp and its inverse Log in §2.3), $\mathcal{P}$ is the set of all partitions, $m_\lambda \in \Lambda$ are the monomial symmetric functions and the product in the denominator on the right hand side is over the cells of $\lambda$ with $a$ and $l$ their arm and leg lengths, respectively.

In this paper we will think of (1.1.1) as the special case $g = 0, k = 2$ of a formula pertaining a genus $g$ Riemann surface with $k$ punctures. Fix integers $g \geq 0$ and $k > 0$. Let $\mathbf{x}_1 = \{x_{1,1}, x_{1,2}, \dots\}, \dots, \mathbf{x}_k = \{x_{k,1}, x_{k,2}, \dots\}$ be $k$ sets of infinitely many independent variables and let $\Lambda(\mathbf{x}_1, \dots, \mathbf{x}_k)$ be the ring of functions separately symmetric in each of the set of variables. When there is no risk of confusion of what variables are involved we will simply write $\Lambda$ for this ring.

Define the *k-point genus g Cauchy function*

$$\Omega(z, w; T) := \sum_{\lambda\in\mathcal{P}} \mathcal{H}_\lambda(z, w) \prod_{i=1}^{k} \tilde{H}_\lambda(\mathbf{x}_i; z^2, w^2), \tag{1.1.2}$$

with coefficients in $\mathbb{Q}(z, w) \otimes_{\mathbb{Z}} \Lambda$, where

$$\mathcal{H}_\lambda(z, w) := \prod \frac{(z^{2a+1} - w^{2l+1})^{2g}}{(z^{2a+2} - w^{2l})(z^{2a} - w^{2l+2})}$$

is a $(z, w)$-deformation of the $(2g - 2)$-th power of the standard hook polynomial. Thus in particular $\Omega(\sqrt{q}, \sqrt{t})$ equals the right hand side of (1.1.1) for $g = 0, k = 2$.

For $\boldsymbol{\mu} = (\mu^1, \dots, \mu^r) \in \mathcal{P}^k$ let

$$\mathbb{H}_{\boldsymbol{\mu}}(z, w) := (z^2 - 1)(1 - w^2) \left\langle \operatorname{Log} \Omega(z, w), h_{\boldsymbol{\mu}} \right\rangle. \tag{1.1.3}$$

Here $h_{\boldsymbol{\mu}} := h_{\mu^1}(\mathbf{x}_1) \cdots h_{\mu^k}(\mathbf{x}_k) \in \Lambda$ are the complete symmetric functions and $\langle \cdot, \cdot \rangle$ is the extended Hall pairing defined in (2.3.1). Recall that $\{m_\lambda\}$ and $\{h_\lambda\}$ are dual bases with respect to the Hall pairing and we may hence recover $\Omega(z, w)$ from the $\mathbb{H}_{\boldsymbol{\mu}}(z, w)$'s by the formula:

$$\Omega(z, w) = \operatorname{Exp}\left(\sum_{\boldsymbol{\mu}\in\mathcal{P}^k} \frac{\mathbb{H}_{\boldsymbol{\mu}}(z, w)}{(z^2 - 1)(1 - w^2)} m_{\boldsymbol{\mu}}\right).$$

Note that $\mathbb{H}_{\boldsymbol{\mu}} = 0$ unless $|\mu^1| = \cdots = |\mu^k|$.

With this notation (1.1.1) is equivalent to

$$\mathbb{H}_{\boldsymbol{\mu}}(z, w) = \begin{cases} 1 & \text{if } \boldsymbol{\mu} = ((1), (1)) \\ 0 & \text{otherwise} \end{cases}. \tag{1.1.4}$$

Fix $\boldsymbol{\mu} = (\mu^1, \dots, \mu^k) \in \mathcal{P}_n{}^k$ for the rest of this introduction where $\mu^i = (\mu^i_1, \mu^i_2, \dots, \mu^i_{r_i})$ and $r_i := \ell(\mu^i)$ is the length of $\mu^i$ ($\mathcal{P}_n$ denotes the set of partitions of $n$). Let $\mathcal{M}_{\boldsymbol{\mu}}$ be a $\mathrm{GL}_n(\mathbb{C})$ character variety of a $k$-punctured genus $g$ Riemann surface, with generic semi-simple conjugacy classes of type $\boldsymbol{\mu}$ at the punctures. In other words, fix semisimple conjugacy classes $C_1, \dots, C_k \subset \mathrm{GL}_n(\mathbb{C})$, which are generic in the sense of

Definition 2.1.1 and have type $\mu^1, \ldots, \mu^k$; i.e., $\{\mu^i_1, \mu^i_2, \ldots\}$ are the multiplicities of the eigenvalues of any matrix in $C_i$. (We prove in Lemma 2.1.2 that there always exist generic semisimple conjugacy classes for every $\boldsymbol{\mu}$.) Let

$$\begin{aligned}\mathcal{M}_{\boldsymbol{\mu}} := \quad & \{A_1, B_1, \ldots, A_g, B_g \in \mathrm{GL}_n(\mathbb{C}), X_1 \in C_1, \ldots, X_k \in C_k | \\ & (A_1, B_1) \cdots (A_g, B_g) X_1 \cdots X_k = I_n\} // \mathrm{GL}_n(\mathbb{C}),\end{aligned}$$

an affine GIT quotient by the conjugation action of $\mathrm{GL}_n(\mathbb{C})$, where for two matrices $A, B \in \mathrm{GL}_n(\mathbb{C})$, we put $(A, B) = ABA^{-1}B^{-1}$ and $I_n$ is the identity matrix. We prove in Theorem 2.1.5 that $\mathcal{M}_{\boldsymbol{\mu}}$ is a non-singular variety of dimension

$$d_{\boldsymbol{\mu}} := n^2(2g - 2 + k) - \sum_{i,j} (\mu^i_j)^2 + 2. \tag{1.1.5}$$

For example, when $k = 1$ and $\boldsymbol{\mu} = ((n))$ $\mathcal{M}_{\boldsymbol{\mu}}$ is just the variety $\mathcal{M}_n$ of [17].

As a natural continuation of [17] here we study the compactly supported mixed Hodge polynomials

$$H_c(\mathcal{M}_{\boldsymbol{\mu}}; x, y, t) := \sum h_c^{i,j;k}(\mathcal{M}_{\boldsymbol{\mu}}) x^i y^j t^k,$$

where $h_c^{i,j;k}(\mathcal{M}_{\boldsymbol{\mu}})$ are the compactly supported mixed Hodge numbers of [4, 5]. For any variety $X/\mathbb{C}$ the polynomial $H_c(X; x, y, t)$ is a common deformation of its compactly supported Poincaré polynomial $P_c(X; t) = H_c(X; 1, 1, t)$ and its so-called $E$-polynomial $E(X; x, y) = H_c(X; x, y, -1)$.

**Conjecture 1.1.1.** *The polynomial* $H_c(\mathcal{M}_{\boldsymbol{\mu}}; x, y, t)$ *depends only on* $xy$ *and* $t$. *If we let* $H_c(\mathcal{M}_{\boldsymbol{\mu}}; q, t) := H_c(\mathcal{M}_{\boldsymbol{\mu}}; \sqrt{q}, \sqrt{q}, t)$ *then*

$$H_c(\mathcal{M}_{\boldsymbol{\mu}}; q, t) = (t\sqrt{q})^{d_{\boldsymbol{\mu}}} \, \mathbb{H}_{\boldsymbol{\mu}}\left(-\frac{1}{\sqrt{q}}, t\sqrt{q}\right).$$

In this paper we will present several consistency checks and prove several implications of this conjecture. For $k = 1$ and $\mu^1 = (n)$ Conjecture 1.1.1 reduces to [17, Conjecture 4.2.1] since, as mentioned, $\mathcal{M}_{\boldsymbol{\mu}} = \mathcal{M}_n$ in this case. For $g = 0$ and $k = 2$ the Cauchy formula (1.1.1) or equivalently (1.1.4) implies Conjecture 1.1.1 as in this case

$$\mathcal{M}_{\boldsymbol{\mu}} := \begin{cases} \text{point} & \text{if } \boldsymbol{\mu} = ((1), (1)) \\ \emptyset & \text{otherwise.} \end{cases}$$

In particular, due to the known symmetry $\tilde{H}_\lambda(\mathbf{x}_i; q, t) = \tilde{H}_{\lambda'}(\mathbf{x}_i; t, q)$ ([10, Corollary 3.2]) of Macdonald polynomials, we have that the right hand side of (1.1.3) is invariant both under changing $(z, w)$ to $(w, z)$ and under changing $(z, w)$ to $(-z, -w)$. Hence the same holds for $\mathbb{H}_{\boldsymbol{\mu}}(z, w)$ and Conjecture 1.1.1 implies

**Conjecture 1.1.2** (Curious Poincaré Duality)**.**

$$H_c\left(\mathcal{M}_{\boldsymbol{\mu}}; \frac{1}{qt^2}, t\right) = (qt)^{-d_{\boldsymbol{\mu}}} H_c(\mathcal{M}_{\boldsymbol{\mu}}; q, t)$$

Here we list our three main results:

## 1.2 Character Variety

**Theorem 1.2.1.** *The polynomial* $E(\mathcal{M}_{\boldsymbol{\mu}}; x, y) = H_c(\mathcal{M}_{\boldsymbol{\mu}}; x, y, -1)$ *depends only on* $xy$ *and if we let* $E(\mathcal{M}_{\boldsymbol{\mu}}; q) := E(\mathcal{M}_{\boldsymbol{\mu}}; \sqrt{q}, \sqrt{q})$ *then*

$$E(\mathcal{M}_{\boldsymbol{\mu}}; q) = H_c(\mathcal{M}_{\boldsymbol{\mu}}; q, -1) = q^{\frac{1}{2}d_{\boldsymbol{\mu}}} \, \mathbb{H}_{\boldsymbol{\mu}}\left(\frac{1}{\sqrt{q}}, \sqrt{q}\right)$$

The calculation of $E(\mathcal{M}_\mu; q)$ follows the same route as in [17]. We prove that $\mathcal{M}_\mu$ is polynomial count and hence by Katz's theorem [17, Theorem 6.1.2.3] $E(\mathcal{M}_\mu; q) = \#\{\mathcal{M}_\mu(\mathbb{F}_q)\}$. To count the points of $\mathcal{M}_\mu$ over a finite field we use the mass formula

$$\#\{\mathcal{M}_\mu(\mathbb{F}_q)\} = \sum_{\chi \in \mathrm{Irr}(\mathrm{GL}_n(\mathbb{F}_q))} \frac{|\mathrm{GL}_n(\mathbb{F}_q)|^{2g-2}(q-1)}{\chi(1)^{2g-2}} \prod_i \frac{\chi(C_i)}{\chi(1)} |C_i| \tag{1.2.1}$$

originally due to Frobenius [8] for $g = 0$. The evaluation of the formula is facilitated by the combinatorial understanding of the character table of $\mathrm{GL}_n(\mathbb{F}_q)$ first obtained in [11].

## 1.3 Quiver Variety

For our second main result we need to introduce a new variety. For $i = 1, \ldots, k$ let $O_i \subset \mathfrak{gl}_n(\mathbb{C})$ be a semisimple adjoint orbit in the Lie algebra $\mathfrak{gl}_n(\mathbb{C})$ of type $\mu^i$; as before, this means that $\{\mu^i_1, \mu^i_2, \ldots\}$ are the multiplicities of the eigenvalues of any matrix in $O_i$. We will call the collection $(O_1, \ldots, O_k)$ generic, if certain linear equations among the eigenvalues of the conjugacy classes are not satisfied (see Definition 2.2.1). There exists a generic collection of conjugacy classes of type $\boldsymbol{\mu}$ if and only if $\boldsymbol{\mu}$ is indivisible (i.e. $\gcd(\{\mu^i_j\}) = 1$). For a generic $(O_1, \ldots, O_k)$ we define

$$\begin{aligned} \mathcal{Q}_\mu := \quad & \{A_1, B_1, \ldots, A_g, B_g \in \mathfrak{gl}_n(\mathbb{C}), C_1 \in O_1, \ldots, C_k \in O_k | \\ & [A_1, B_1] + \cdots + [A_g, B_g] + C_1 \cdots + C_k = 0\} /\!/ \mathrm{GL}_n(\mathbb{C}), \end{aligned}$$

an affine GIT quotient by the conjugation action of $\mathrm{GL}_n(\mathbb{C})$, where $[\cdot,\cdot]$ is the Lie bracket in $\mathfrak{gl}_n(\mathbb{C})$. We prove in Theorem 2.2.4 that $\mathcal{Q}_\mu$ is a smooth variety of dimension $d_\mu$. It is a quiver variety in the sense of Nakajima and Crawley-Boevey associated to the comet-shaped quiver $\Gamma$ consisting of $g$ loops on a central vertex and $k$ legs of length $\ell(\mu^i)$. See §2.2 for more details.

**Theorem 1.3.1.** *For $\boldsymbol{\mu}$ indivisible the mixed Hodge structure on $H^*_c(\mathcal{Q}_\mu)$ is pure, in other words, $h^{i,j;k}(\mathcal{Q}_\mu) = 0$ unless $i + j = k$, and $E(\mathcal{Q}_\mu; x, y)$ only depends on the product $xy$. If we let $E(\mathcal{Q}_\mu; q) := E(\mathcal{Q}_\mu; \sqrt{q}, \sqrt{q})$ then*

$$P_c(\mathcal{Q}_\mu; \sqrt{q}) = E(\mathcal{Q}_\mu; q) = q^{\frac{1}{2}d_\mu}\, \mathbb{H}_\mu\left(0, \sqrt{q}\right), \tag{1.3.1}$$

*where $P_c(\mathcal{Q}_\mu, t)$ is the compactly supported Poincaré polynomial of $\mathcal{Q}_\mu$.*

As in the multiplicative case, Katz's theorem [17, Theorem 6.1.2.3] implies that $E(\mathcal{Q}_\mu; q) = \#\{\mathcal{Q}_\mu(\mathbb{F}_q)\}$. The calculation of the number of points on the right is performed using the mass formula

$$\#\{\mathcal{Q}_\mu(\mathbb{F}_q)\} = \frac{|\mathfrak{gl}_n(\mathbb{F}_q)|^{g-1}}{|\mathrm{PGL}_n(\mathbb{F}_q)|} \sum_{x \in \mathfrak{gl}_n(\mathbb{F}_q)} |C_{\mathfrak{gl}_n(\mathbb{F}_q)}(x)|^g \prod_{i=1}^k \mathcal{F}^{\mathfrak{g}}(1_{O_i})(x), \tag{1.3.2}$$

where $C_{\mathfrak{gl}_n(\mathbb{F}_q)}(x)$ denotes the centralizer of $x$ in $\mathfrak{gl}_n(\mathbb{F}_q)$.

The evaluation of this sum is based on a combinatorial understanding of the formulas in [28] in the case of $\mathfrak{gl}_n(\mathbb{F}_q)$. One can consider Theorem 1.3.1 as further evidence for Conjecture 1.1.1, at least in the light of the *purity conjecture* $PH_c(\mathcal{M}_\mu; q) = E(\mathcal{Q}_\mu; q)$ of [14], where $PH_c(\mathcal{M}_\mu; q) := \sum_i h_c^{i,i;2i}(\mathcal{M}_\mu) q^i$ is the pure part of $H_c(\mathcal{M}_\mu; q)$. Conjecture 1.1.1 implies that the right hand side of (1.3.1) equals $PH_c(\mathcal{M}_\mu; q)$. In general then, taking the pure part should correspond to the evaluation $z = 0, w = \sqrt{q}$. For example, the pure part of the Macdonald symmetric function is $\tilde{H}_\lambda(\mathbf{x}; w) := \tilde{H}_\lambda(\mathbf{x}; 0, w)$ a (transformed version of) the Hall-Littlewood symmetric function. Thus Theorem 1.3.1 shows that the $E$-polynomials of the above quiver varieties are closely related to the generalized Cauchy formula for Hall-Littlewood functions.

## 1.4 Multiplicities

For our third main theorem we need to introduce some complex irreducible characters of $G := \mathrm{GL}_n(\mathbb{F}_q)$. Pick distinct linear characters $\alpha_{i,1}, \ldots, \alpha_{i,r_i}$ of $\mathbb{F}_q^\times$ for each $i$. Consider the subgroup $L_i := \prod_{j=1}^{r_i} \mathrm{GL}_{\mu^i_j}(\mathbb{F}_q)$ of $G$ and the linear character $\tilde{\alpha}_i := \prod_{j=1}^{r_i}(\alpha_{i,j} \circ \det)$ of $L_i$. We get an irreducible character of $G$ by taking the Lusztig induction $R_{L_i}^G(\tilde{\alpha}_i)$. We assume now that the $\alpha_{i,j}$'s are chosen such that the $k$-tuple $(R_{L_1}^G(\tilde{\alpha}_1), \ldots, R_{L_k}^G(\tilde{\alpha}_k))$ is *generic* in the sense of Definition 4.2.2 (such a choice is possible for every $\boldsymbol{\mu}$). To simplify the notation we let

$$R_{\boldsymbol{\mu}} := \bigotimes_{i=1}^{k} R_{L_i}^G(\tilde{\alpha}_i).$$

Let $\Lambda : G \to \mathbb{C}$ be defined by $x \mapsto q^{g \dim C_G(x)}$, where $C_G(x)$ is the centralizer of $x$ in $G$. If $g = 1$, it is the character of the permutation representation where $G$ acts on the set $\mathfrak{gl}_n(\mathbb{F}_q)$ by conjugation.

**Theorem 1.4.1.** *The following identity holds*

$$\mathbb{H}_{\boldsymbol{\mu}}(0, \sqrt{q}) = \left\langle \Lambda \otimes R_{\boldsymbol{\mu}}, 1 \right\rangle \tag{1.4.1}$$

*where $\langle\ ,\ \rangle$ is the usual scalar product of characters.*

**Corollary 1.4.2.** *For $\boldsymbol{\mu}$ indivisible the following are equivalent:*

*a)* $\left\langle \Lambda \otimes R_{\boldsymbol{\mu}}, 1 \right\rangle = 0$.

*b) The quiver variety $\mathcal{Q}_{\boldsymbol{\mu}}$ is empty.*

In the genus $g = 0$ case, the problem of deciding whether $\mathcal{Q}_{\boldsymbol{\mu}}$ is empty was solved by Kostov [24][25]. Later on, Crawley-Boevey [2] reformulated Kostov's answer in terms of roots. Namely he proved that $\mathcal{Q}_{\boldsymbol{\mu}}$ is non-empty if and only if $\alpha$, the dimension vector for $\Gamma$ with dimension $\sum_{j=1}^{l} \mu^i_j$ at the $l$-th vertex on the $i$-th leg, is a root of the Kac-Moody algebra associated to $\Gamma$.

Consider now the number $A_{\boldsymbol{\mu}}(q)$ of absolutely indecomposable representations of $\Gamma$ of dimension $\alpha$ over the finite field $\mathbb{F}_q$ (up to isomorphism). Kac [21] proved that $A_{\boldsymbol{\mu}}(q)$ is a polynomial in $q$ with integer coefficients and conjectured that these coefficients are non-negative [20, Conjecture 2]. Crawley-Boevey and Van den Bergh proved [3] this latter conjecture precisely in the case when $\alpha$ is indivisible (i.e. when $\boldsymbol{\mu}$ is indivisible) by giving a cohomological interpretation for $A_{\boldsymbol{\mu}}(q)$. In our case their result says that for $\boldsymbol{\mu}$ indivisible $E(\mathcal{Q}_{\boldsymbol{\mu}}; q) = q^{\frac{1}{2}d_{\boldsymbol{\mu}}} A_{\boldsymbol{\mu}}(q)$. This result together with Theorem 1.3.1 and Theorem 1.4.1 implies

$$A_{\boldsymbol{\mu}}(q) = \mathbb{H}_{\boldsymbol{\mu}}(0, \sqrt{q}) = \left\langle \Lambda \otimes R_{\boldsymbol{\mu}}, 1 \right\rangle \tag{1.4.2}$$

when $\boldsymbol{\mu}$ is indivisible. In [15] we prove the equality (1.4.2) for *any* $\boldsymbol{\mu}$. Assuming Conjecture 1.1.1, this gives a cohomological interpretation of both $\left\langle \Lambda \otimes R_{\boldsymbol{\mu}}, 1 \right\rangle$ and $A_{\boldsymbol{\mu}}(q)$ for comet-shaped quivers, which in particular, implies Kac's conjecture on the coefficients of $A_{\boldsymbol{\mu}}(q)$ for such quivers.

As a final remark, we would like to bring to the reader's attention some recent related work. The first Kac conjecture [20, Conjecture 1], asserting that the constant term of the $A$-polynomial of a quiver is a certain multiplicity in the corresponding Kac-Moody algebra, has recently been proved for any loop-free quiver in [13] using Nakajima quiver varieties and techniques closely related to the ones in this paper. The manuscript [18] studies the $A$-polynomials from a point of view motivated by [17] and this paper.

**Acknowledgements.** We organized a workshop bearing the title of this paper, at the American Institute of Mathematics in Palo Alto in June 2007. We would like to thank the Institute's staff for their help with the organization and the participants of the conference for the many talks and discussions, from which we learnt a lot. TH was supported by NSF grants DMS-0305505, DMS-0604775 an Alfred Sloan Fellowship 2005-2007 and a Royal Society University Research Fellowship since 2005; FRV was supported by NSF grant DMS-0200605.

# 2 Generalities

## 2.1 Character varieties

Fix integers $g \geq 0$, $k, n > 0$. We also fix a $k$-tuple of partitions of $n$ which we denote by $\boldsymbol{\mu} = (\mu^1, \ldots, \mu^k) \in \mathcal{P}_n^k$, i.e. $\mu^i = (\mu^i_1, \mu^i_2, \ldots)$ such that $\mu^i_1 \geq \mu^i_2 \geq \ldots$ are non-negative integers and $\sum_j \mu^i_j = n$. Finally, let $\mathbb{K}$ be an algebraically closed field such that

$$\operatorname{char}(\mathbb{K}) \nmid \gcd\{\mu^i_j\}. \tag{2.1.1}$$

We now construct a variety whose points parametrize representations of the fundamental group of a $k$-punctured Riemann surface of genus $g$ into $\mathrm{GL}_n(\mathbb{K})$ with prescribed images in semisimple conjugacy classes $C_1, \ldots, C_k$ at the punctures. Assume that

$$\prod_{i=1}^{k} \det C_i = 1 \tag{2.1.2}$$

and that $(C_1, C_2, \ldots, C_k)$ has type $\boldsymbol{\mu} = (\mu^1, \mu^2, \ldots, \mu^k)$; i.e., $C_i$ has type $\mu^i$ for each $i = 1, 2, \ldots, k$, where the *type* of a semisimple conjugacy class $C \subset \mathrm{GL}_n(\mathbb{K})$ is defined as the partition $\mu = (\mu_1, \mu_2, \ldots) \in \mathcal{P}_n$ describing the multiplicities of the eigenvalues of (any matrix in) $C$.

**Definition 2.1.1.** The $k$-tuple $(C_1, \ldots, C_k)$ is *generic* if the following holds. If $V \subseteq \mathbb{K}^n$ is a subspace stable by some $X_i \in C_i$ for each $i$ such that

$$\prod_{i=1}^{k} \det(X_i|_V) = 1 \tag{2.1.3}$$

then either $V = 0$ or $V = \mathbb{K}^n$.

For example, if $k = 1$ and $C_1$ is of type $(n^1)$ i.e. consists of the diagonal matrix of eigenvalue $\zeta$ (with $\zeta^n = 1$ so that (2.1.2) is satisfied) then $C$ is generic if and only if $\zeta$ is a *primitive* $n$-th root of 1.

**Lemma 2.1.2.** *There exists a generic k-tuple of semisimple conjugacy classes* $(C_1, \ldots, C_k)$ *of type* $\boldsymbol{\mu}$ *over* $\mathbb{K}$.

*Proof.* Let $A := \mathbb{G}_m^{r_1} \times \cdots \times \mathbb{G}_m^{r_k}$ over $\mathbb{K}$. For any $\boldsymbol{\nu} = (\nu^1, \ldots, \nu^k) = (\nu^i_j) \in \mathbb{Z}^{r_1} \times \cdots \times \mathbb{Z}^{r_k}$ define the homomorphism

$$\begin{array}{rcl} \phi_{\boldsymbol{\nu}} : A & \longrightarrow & \mathbb{G}_m \\ (a^i_j) & \mapsto & \prod_{i,j} (a^i_j)^{\nu^i_j} \end{array}$$

and set $A_{\boldsymbol{\nu}} := \ker \phi_{\boldsymbol{\nu}}$. By hypothesis $\operatorname{char}(\mathbb{K}) \nmid d$ and hence $\mathbb{K}$ contains a primitive $d$-th root of unity $\zeta_d$. Let $A'$ be defined by

$$A' : \qquad \prod_{i,j} (a^i_j)^{\mu^i_j / d} = \zeta_d.$$

Observe that $u := (\mu^i_j/d)_{i,j}$ is a primitive vector in $\mathbb{Z}^{r_1} \times \cdots \times \mathbb{Z}^{r_k}$. Hence we can change coordinates in this lattice so that $u$ is part of a basis. In the corresponding new variables of $A$ the equation defining $A'$ is simply $a_1 = \zeta_d$ and therefore $A' \cong (\mathbb{G}_m^{\times})^{\sum r_i - 1}$, showing it is irreducible. Thus $A'$ is a connected component of $A_{\boldsymbol{\mu}}$.

Now if $A' \subseteq A_{\boldsymbol{\nu}}$ then $A_{\boldsymbol{\mu}} \subseteq A_{\boldsymbol{\nu}}$ as $A'$ generates $A_{\boldsymbol{\mu}}$. But $A_{\boldsymbol{\mu}} \subseteq A_{\boldsymbol{\nu}}$ implies $l\boldsymbol{\mu} = \boldsymbol{\nu}$ for some $l \in \mathbb{Z}_{\geq 0}$, since $\operatorname{char}(\mathbb{K})$ does not divide $d = \gcd(\mu^i_j)$. So $A'_{\boldsymbol{\nu}} := A' \cap A_{\boldsymbol{\nu}} \subseteq A'$ is a proper Zariski closed subset of the irreducible space $A'$ for every $\boldsymbol{\nu} = (\nu^i_j)$ with $0 \leq \nu^i_j \leq \mu^i_j$ different from $\boldsymbol{\mu}$ and $\mathbf{0}$. The same is true for all the subgroups $B$ determined by the equalities $a^i_{j_1} = a^i_{j_2}$ for $j_1 \neq j_2$. Hence the union of all $A'_{\boldsymbol{\nu}}$ and all $B$'s is not equal to the irreducible $A'$ and the complement contains a $\mathbb{K}$-point. $\square$

For a $k$-tuple of conjugacy classes $(\mathcal{C}_1, \ldots, \mathcal{C}_k)$ of type $\boldsymbol{\mu}$ define $\mathcal{U}_{\boldsymbol{\mu}}$ as the subvariety of $\mathrm{GL}_n(\mathbb{K})^{2g+k}$ of elements $(A_1, \ldots, A_g, B_1, \ldots, B_g, X_1, \ldots, X_k)$ which satisfy

$$(A_1, B_1) \cdots (A_g, B_g) X_1 \cdots X_k = I_n, \qquad X_i \in \mathcal{C}_i. \tag{2.1.4}$$

In §7.1 we describe the defining equations of $\mathcal{U}_{\boldsymbol{\mu}}$, showing that it is indeed an affine variety.

*Remark* 2.1.3. If $\Sigma_g$ is a compact Riemann surface of genus $g$ with punctures $S = \{s_1, \ldots, s_k\} \subseteq \Sigma_g$ then $\mathcal{U}_\mu$ can be identified with the set

$$\{\rho \in \mathrm{Hom}\left(\pi_1(\Sigma_g \setminus S), \mathrm{GL}_n(\mathbb{K})\right) \mid \rho(\gamma_i) \in \mathcal{C}_i\},$$

(for some choice of base point, which we omit from the notation). Here we use the standard presentation

$$\pi_1(\Sigma_g \setminus S) = \langle \alpha_1 \ldots, \alpha_g; \beta_1 \ldots, \beta_g; \gamma_1 \ldots, \gamma_g \mid (\alpha_1, \beta_1) \cdots (\alpha_g, \beta_g)\gamma_1 \cdots \gamma_k = 1 \rangle$$

($\gamma_i$ is the class of a simple loop around $s_i$ with orientation compatible with that of $\Sigma_g$).

We have $\mathrm{GL}_n$ acting on $\mathrm{GL}_n^{2g+k}$ by conjugation. As the center acts trivially this induces an action of $\mathrm{PGL}_n$. The action also leaves (2.1.4), the defining equations of $\mathcal{U}_\mu$ invariant, thus induces an action of $\mathrm{PGL}_n$ on $\mathcal{U}_\mu$. We call the affine GIT quotient

$$\mathcal{M}_\mu := \mathcal{U}_\mu // \mathrm{PGL}_n = \mathrm{Spec}(\mathbb{K}[\mathcal{U}_\mu]^{\mathrm{PGL_n}})$$

*a generic character variety* of type $\boldsymbol{\mu}$. We denote by $\pi_\mu$ the quotient morphism

$$\pi_\mu : \mathcal{M}_\mu \to \mathcal{U}_\mu.$$

**Proposition 2.1.4.** *If $(\mathcal{C}_1, \ldots, \mathcal{C}_k)$ is generic of type $\boldsymbol{\mu}$ then the group $\mathrm{PGL}_n(\mathbb{K})$ acts set-theoretically freely on $\mathcal{U}_\mu$ and every point of $\mathcal{U}_\mu$ corresponds to an irreducible representation of $\pi_1(\Sigma_g \setminus S)$.*

*Proof.* Let $A_1, B_1, \ldots, A_g, B_g \in \mathrm{GL}_n(\mathbb{K})$ and $X_i \in \mathcal{C}_i$ satisfy

$$(A_1, B_1) \cdots (A_g, B_g) X_1 \cdots X_k = I_n. \tag{2.1.5}$$

Assume that all the matrices $A_i, B_i$ and $X_j$ preserve a subspace $V \subseteq \mathbb{K}^n$. Let $A_i' = A_i|_V$, $B_i' = B_i|_V$ and $X_i' = X_i|_V$. Then

$$(A_1', B_1') \cdots (A_g', B_g') X_1' \cdots X_k' = I_V. \tag{2.1.6}$$

Taking determinants of both sides we see that the product of the eigenvalues of the matrices $X_i'$ equals 1. Hence, by the genericity assumption, either $V = 0$ or $V = \mathbb{K}^n$ and the corresponding representation of $\pi_1(\Sigma_g \setminus S)$ is irreducible.

Now suppose $g \in \mathrm{GL}_n(\mathbb{K})$ commutes with all the matrices $A_i, B_i$ and $X_j$. By the irreducibility of the action we just proved it follows from Schur's lemma that $g \in \mathrm{GL}_n(\mathbb{K})$ is a scalar. Hence $\mathrm{PGL}_n(\mathbb{K})$ acts set-theoretically freely on $\mathcal{U}_\mu(\mathbb{K})$. □

**Theorem 2.1.5.** *If $(\mathcal{C}_1, \ldots, \mathcal{C}_k)$ is a generic k-tuple of semisimple conjugacy classes in $\mathrm{GL}_n(\mathbb{K})$ of type $\boldsymbol{\mu}$ then the quotient $\pi_\mu : \mathcal{U}_\mu \to \mathcal{M}_\mu$ is a* geometric quotient *and a $\mathrm{PGL}_n$ principle bundle. Consequently, the variety $\mathcal{M}_\mu$ is non-singular of pure dimension $d_\mu$, i.e., it is the disjoint union of its irreducible components all non-singular of same dimension $d_\mu$.*

*Proof.* If $k = 1$ and $\mathcal{C}_1$ is a central matrix, this is [17, Theorem 2.2.5], if $g = 0$ and $\mathbb{K} = \mathbb{C}$ then this is [7, Proposition 5.2.8]. Our proof will combine the proofs of these two results.

Let

$$\rho : \mathrm{GL}_n(\mathbb{K})^{2g} \times \mathcal{C}_1 \times \ldots \times \mathcal{C}_k \to \mathrm{SL}_n(\mathbb{K})$$

be given by

$$(A_1, B_1, A_2, B_2, \ldots, A_g, B_g, X_1, \ldots, X_k) \mapsto (A_1, B_1) \ldots (A_k, B_k) X_1 \ldots X_k.$$

We have $\mathcal{U}_\mu = \rho^{-1}(I_n)$. Combining the calculations in [17, Theorem 2.2.5] and [7, Proposition 5.2.8] it is straightforward, albeit lengthy, to calculate the differential $d_s\rho$; we leave it to the reader. Exactly as in [loc. cit] we can then argue that $d_s\rho$ is surjective for all $s \in \mathcal{U}_\mu$ and so the affine variety $\mathcal{U}_\mu$ is non-singular of dimension

$$\dim \left(\mathrm{GL}_n(\mathbb{K}))^{2g} \times C_1 \times \ldots \times C_k\right) - \dim \mathrm{SL}_n(\mathbb{K}) = 2gn^2 + kn^2 - n^2 + 1 - \sum_{i,j} \left(\mu^i_j\right)^2.$$

Exactly as in [17, Corollaries 2.2.7, 2.2.8] we can argue that this is a geometric quotient as well as a $\mathrm{PGL}_n$ principal bundle, proving that $\mathcal{M}_\mu$ is non-singular of dimension $d_\mu$ given by (1.1.5). $\square$

## 2.2 Quiver varieties

As in §2.1 we fix $g, k, n, \boldsymbol{\mu}$. But in this section we take an algebraically closed field $\mathbb{K}$, which satisfies

$$\mathrm{char}(\mathbb{K}) \nmid D! \tag{2.2.1}$$

where $D = \min_i \max_j \mu^i_j$. For $i = 1, \ldots, k$ let $\mathcal{O}_i \subset \mathfrak{gl}_n$ be a semisimple adjoint orbit satisfying

$$\sum_{i=1}^{k} \mathrm{Tr}\, \mathcal{O}_i = 0. \tag{2.2.2}$$

Let $a_{i,1}, \ldots, a_{i,r_i}$ be the distinct eigenvalues of $\mathcal{O}_i$, and let $\mu^i_j$ be the multiplicity of $a^i_j$. We assume that $\mu^i_1 \geq \ldots \geq \mu^i_{r_i}$. As in the previous section, we assume that the multiplicities $\{\mu^i_j\}_j$ determine our fixed partitions $\mu^i$ of $n$ which is called the type of $\mathcal{O}_i$, and $\boldsymbol{\mu} := (\mu^1, \ldots, \mu^k)$ is called the type of $(\mathcal{O}_1, \ldots, \mathcal{O}_k)$.

**Definition 2.2.1.** The $k$-tuple $(\mathcal{O}_1, \ldots, \mathcal{O}_k)$ of semisimple adjoint orbits is *generic* if the following holds. If $V \subseteq \mathbb{K}^n$ is a subspace stable by some $X_i \in \mathcal{O}_i$ for each $i$ such that

$$\sum_{i=1}^{k} \mathrm{Tr}\,(X_i|_V) = 0 \tag{2.2.3}$$

then either $V = 0$ or $V = \mathbb{K}^n$.

Let $d := \gcd\{\mu^i_j\}$. We have the following

**Lemma 2.2.2.** *Assume* (2.2.1). *If $d > 1$ generic $k$-tuples of adjoint orbits of type $\boldsymbol{\mu}$ do not exist. If $d = 1$, in which case we say that $\boldsymbol{\mu}$ is* indivisible, *they do.*

*Proof.* In terms of eigenvalues (2.2.2) is equivalent to $\sum_{i,j} a^i_j \mu^i_j = 0$. If $d > 1$ then it is easy to construct for a fixed basis in $\mathbb{K}^n$ diagonal matrices $X_i \in \mathcal{O}_i$ and $V \subset \mathbb{K}^n$ of dimension $n/d$ such that

$$\sum_i \mathrm{Tr}(X_i|_V) = \sum_{i,j} a^i_j \frac{\mu^i_j}{d} = 0.$$

This shows the first part of our Lemma.

Phrased in terms of the eigenvalues of a matrix in $\mathcal{O}_i$, in the indivisible case we are looking for a point in the complement of a hyperplane arrangement in $\mathbb{K}^{\sum r_i - 1}$. (The hyperplanes do not degenerate due to the assumption (2.2.1).) As $\mathbb{K}^{\sum r_i - 1}$ is irreducible such a point exists. (In the present, additive, case we do not have the crutch of a $d$-th torsion point as we did in Lemma 2.1.2.) $\square$

For a $k$-tuple of semisimple adjoint orbits $(\mathcal{O}_1, \ldots, \mathcal{O}_k)$ of type $\boldsymbol{\mu}$ define $\mathcal{V}_{\mu}$ as the subvariety of $\mathfrak{gl}_n(\mathbb{K})^{2g+k}$ of matrices $(A_1, \ldots, A_g, B_1, \ldots, B_g, X_1, \ldots, X_k)$ which satisfy

$$[A_1, B_1] + \cdots + [A_g, B_g] + X_1 + \cdots + X_k = 0, \qquad X_i \in \mathcal{O}_i, \tag{2.2.4}$$

where $[\cdot, \cdot]$ is the Lie bracket in $\mathfrak{gl}_n(\mathbb{K})$. As explained in Remark 7.1.2 one can define $\mathcal{V}_{\mu}$ by equations showing that it is indeed an affine variety.

**Proposition 2.2.3.** *If $(\mathcal{O}_1, \ldots, \mathcal{O}_k)$ is generic then* $\mathrm{PGL}_n(\mathbb{K})$ *acts set-theoretically freely on $\mathcal{V}_{\mu}$ and for any element $(A_1, B_1, \ldots, A_g, B_g, X_1, \ldots, X_k) \in \mathcal{V}_{\mu}$ there is no non-zero proper subspace of $\mathbb{K}^n$ stable by $A_1, B_1, \ldots, A_g, B_g, X_1, \ldots, X_k$.*

*Proof.* Similar to that of Proposition 2.1.4. □

$\mathrm{GL}_n$ acts on $\mathcal{V}_{\mu}$ by simultaneously conjugating the matrices in the defining equation (2.2.4) of $\mathcal{V}_{\mu}$. We can thus construct an affine *quiver variety* of type $\boldsymbol{\mu}$ as the affine GIT quotient

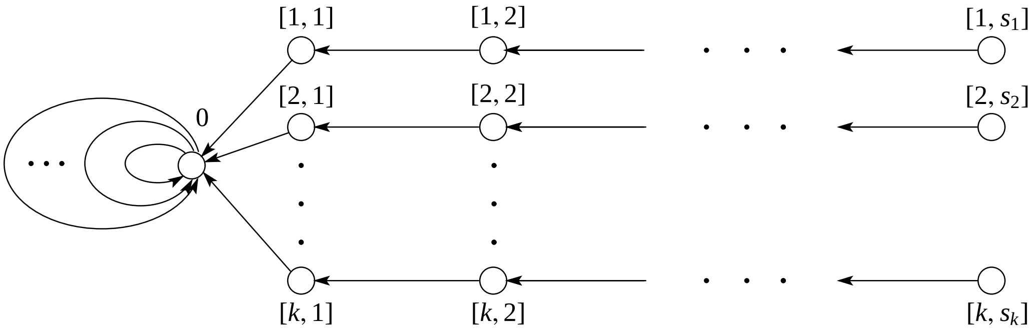
$$\mathcal{Q}_{\mu} := \mathcal{V}_{\mu} // \mathrm{PGL}_n = \mathrm{Spec}(\mathbb{K}[\mathcal{V}_{\mu}]^{\mathrm{PGL}_n}).$$

In Theorem 2.2.5 below we will prove that $\mathcal{Q}_{\mu}$ is isomorphic to a quiver variety associated to a certain comet-shaped quiver, hence its name.

**Theorem 2.2.4.** *If $(\mathcal{O}_1, \ldots, \mathcal{O}_k)$ is generic then the variety $\mathcal{Q}_{\mu}$ is non-singular of dimension $d_{\mu}$. Moreover, $\mathcal{V}_{\mu} // \mathrm{PGL}_n(\mathbb{K})$ is a geometric quotient and the quotient map $\mathcal{V}_{\mu} \to \mathcal{Q}_{\mu}$ is a principal* $\mathrm{PGL}_n$ *bundle.*

*Proof.* The proof is similar to that of Theorem 2.1.5. □

We now review the connection between $\mathcal{Q}_{\mu}$ and quiver representations due to Crawley-Boevey [2]. Let $\mathbf{s} = (s_1, \ldots, s_k) \in \mathbb{Z}^k_{\geq 0}$. Put $I = \{0\} \cup \{[i, j]\}_{1 \leq i \leq k, 1 \leq j \leq s_i}$ and let $\Gamma$ be the quiver with $g$ loops on the central vertex represented as below[1]:



A *dimension vector* for $\Gamma$ is a collection of non-negative integers $\mathbf{v} = \{v_i\}_{i \in I} \in \mathbb{Z}^I_{\geq 0}$ and a representation of $\Gamma$ of dimension $\mathbf{v}$ over $\mathbb{K}$ is a collection of $\mathbb{K}$-linear maps $\phi_{i,j} : \mathbb{K}^{v_i} \to \mathbb{K}^{v_j}$ for each arrow $i \to j$ of $\Gamma$ that we identify with matrices (using the canonical basis of $\mathbb{K}^r$). Let $\Omega$ be a set indexing the edges of $\Gamma$. For $\gamma \in \Omega$, let $h(\gamma), t(\gamma) \in I$ denote respectively the head and the tail of $\gamma$. The algebraic group $\prod_{i \in I} \mathrm{GL}_{v_i}(\mathbb{K})$ acts on the space

$$\mathrm{Rep}_{\mathbb{K}}(\Gamma, \mathbf{v}) := \bigoplus_{\gamma \in \Omega} \mathrm{Mat}_{v_{h(\gamma)}, v_{t(\gamma)}}(\mathbb{K})$$

---

[1] The picture is from [36].

of representations of dimension $\mathbf{v}$ in the obvious way. As the diagonal center $(\lambda I_{v_i})_{i\in I} \in \left(\prod_{i\in I} \mathrm{GL}_{v_i}(\mathbb{K})\right)$ acts trivially the action reduces to an action of

$$\mathrm{G}_{\mathbf{v}}(\mathbb{K}) := \left(\prod_{i\in I} \mathrm{GL}_{v_i}(\mathbb{K})\right)/\mathbb{K}^{\times}.$$

Clearly two elements of $\mathrm{Rep}_{\mathbb{K}}(\Gamma, \mathbf{v})$ are isomorphic if and only if they are $\mathrm{G}_{\mathbf{v}}(\mathbb{K})$-conjugate.

Let $\overline{\Gamma}$ be the *double quiver* of $\Gamma$ i.e. $\overline{\Gamma}$ has the same vertices as $\Gamma$ but the edges are given by $\overline{\Omega} := \{\gamma, \gamma^* | \gamma \in \Omega\}$ where $h(\gamma^*) = t(\gamma)$ and $t(\gamma^*) = h(\gamma)$. Then via the trace pairing we may identify $\mathrm{Rep}_{\mathbb{K}}(\overline{\Gamma}, \mathbf{v})$ with the cotangent bundle $\mathrm{T}^*\mathrm{Rep}_{\mathbb{K}}(\Gamma, \mathbf{v})$. Define the *moment map*

$$\begin{align} \mu_{\mathbf{v}} : \mathrm{Rep}_{\mathbb{K}}(\overline{\Gamma}, \mathbf{v}) &\to M(\mathbf{v}, \mathbb{K})^0 \tag{2.2.5} \\ (x_\gamma)_{\gamma\in\overline{\Omega}} &\mapsto \sum_{\gamma\in\Omega} [x_\gamma, x_\gamma^*], \tag{2.2.6} \end{align}$$

where

$$M(\mathbf{v}, \mathbb{K})^0 := \left\{ (f_i)_{i\in I} \in \bigoplus_{i\in I} \mathfrak{gl}_{v_i}(\mathbb{K}) | \sum_{i\in I} \mathrm{Tr}(f_i) = 0 \right\}$$

is identified with the dual of the Lie algebra of $\mathrm{G}_{\mathbf{v}}(\mathbb{K})$. It is a $\mathrm{G}_{\mathbf{v}}(\mathbb{K})$-equivariant map. We define a bilinear form on $\mathbb{K}^I$ by $\mathbf{a} \,.\, \mathbf{b} = \sum_i a_i b_i$. For $\boldsymbol{\xi} = (\xi_i)_i \in \mathbb{K}^I$ such that $\boldsymbol{\xi} \,.\, \mathbf{v} = 0$, the element

$$(\xi_i.\mathrm{Id})_i \in \bigoplus_i \mathfrak{gl}_{v_i}(\mathbb{K})$$

is in fact in $M(\mathbf{v}, \mathbb{K})^0$. For such a $\boldsymbol{\xi} \in \mathbb{K}^I$, the affine variety $\mu_{\mathbf{v}}^{-1}(\boldsymbol{\xi})$ is endowed with a $\mathrm{G}_{\mathbf{v}}(\mathbb{K})$- action. We call the affine GIT quotient

$$\mathfrak{M}_{\xi}(\mathbf{v}) := \mu_{\mathbf{v}}^{-1}(\boldsymbol{\xi})//\mathrm{G}_{\mathbf{v}}(\mathbb{K})$$

the affine *quiver variety*. These and related quiver varieties were considered by many authors including Kronheimer, Lusztig, Nakajima and Crawley-Boevey [26, 30, 33, 1].
Following [2], we now identify our $\mathcal{Q}_{\boldsymbol{\mu}}$, constructed from a generic $k$-tuple $(\mathcal{O}_1, \ldots, \mathcal{O}_k)$ of type $\boldsymbol{\mu}$, with a certain quiver variety. We define $\mathbf{s}$ as $s_i = \ell(\mu^i) - 1$ where $\ell(\lambda)$ denotes the length of a partition $\lambda$. Then we define $\mathbf{v} \in \mathbb{Z}^I_{\geq 0}$ as $v_0 = n$ and $v_{[i,j]} = n - \sum_{r=1}^{j} \mu^i_r$ for $[i, j] \in I$. Clearly $n \geq v_{[i,1]} \geq \ldots \geq v_{[i,s_i]}$. We define $\xi \in \mathbb{K}^I$ as $\xi_0 = -\sum_{i=1}^{k} a_{i,1}$ and $\xi_{[i,j]} = a^i_j - a^i_{j+1}$.

For a representation $\varphi \in \mathrm{Rep}_{\mathbb{K}}(\overline{\Gamma}, \mathbf{v})$, and an arrow $[i, j] \to [i, j-1] \in \Omega$ with $1 \leq j \leq s_i$, denote by $\varphi_{[i,j]}$ the corresponding linear map $\mathbb{K}^{v_{[i,j]}} \to \mathbb{K}^{v_{[i,j-1]}}$, and denote by $\varphi_1, \varphi_2, \ldots, \varphi_g$ the linear maps $\mathbb{K}^{v_0} \to \mathbb{K}^{v_0}$ associated to the $g$ loops in $\Omega$. Following [2, Section 3], we construct a surjective algebraic morphism $\omega : \mu_{\mathbf{v}}^{-1}(\boldsymbol{\xi}) \to \mathcal{V}$ which is constant on $\prod_{i\in I-\{0\}} \mathrm{GL}_{v_i}(\mathbb{K})$ orbits. Let $\varphi \in \mu_{\mathbf{v}}^{-1}(\boldsymbol{\xi})$. For each $i \in \{1, \ldots, k\}$, define

$$X_i = \varphi_{[i,1]}\varphi^*_{[i,1]} + a_{i,1}\mathrm{Id} \in \mathrm{Mat}_{v_0}(\mathbb{K}).$$

For $j \in \{1, \ldots, g\}$, put $A_j = \varphi_j$ and $B_j = \varphi_j^*$. We will set

$$\omega(\phi) := (A_1, B_1, \ldots, A_g, B_g, X_1, \ldots, X_k). \tag{2.2.7}$$

To show that $\omega(\phi) \in \mathcal{V}$ recall that $\mu$ at the vertex 0 is given

$$\sum_{j=1}^{g} [\varphi_j, \varphi_j^*] + \sum_{i=1}^{k} \varphi_{[i,1]}\varphi^*_{[i,1]} = \xi_0 \mathrm{Id}$$

which gives

$$\sum_{j=1}^{g} [A_i, B_i] + \sum_{i=1}^{k} X_i = 0.$$

It is straightforward to see [2, Section 3] that we have $X_i \in \mathcal{O}_i$ for all $i \in \{1, \ldots, k\}$ from which we deduce that indeed

$$(A_1, B_1, \ldots, A_g, B_g, X_1, \ldots, X_k) \in \mathcal{V}.$$

The map $\omega$ induces a bijection between isomorphic classes of simple representations in $\mu_{\mathbf{v}}^{-1}(\boldsymbol{\xi})$ and the $\mathrm{GL}_n(\mathbb{K})$-conjugacy classes of the set of tuples $(A_1, B_1, \ldots, A_g, B_g, X_1, \ldots, X_k) \in \mathcal{V}$ thus we have [2]:

**Theorem 2.2.5.** *The map $\omega$ in* (2.2.7) *induces an isomorphism $\mathfrak{M}_\xi(\mathbf{v}) \simeq \mathcal{Q}_\mu$.*

**Proposition 2.2.6.** *Let $\mathbb{K} = \mathbb{C}$. If $(\mathcal{O}_1, \ldots, \mathcal{O}_k)$ is generic the mixed Hodge structure of the cohomology $H^*(\mathcal{Q}_\mu)$ of the quiver variety $\mathcal{Q}_\mu$ is pure.*

*Proof.* We will construct a non-singular variety $\mathfrak{M}$ with a smooth map $f : \mathfrak{M} \to \mathbb{C}$ such that for $0 \neq \lambda \in \mathbb{C}$ the preimage $f^{-1}(\lambda) \simeq \mathfrak{M}_\xi(\mathbf{v}) \simeq \mathcal{Q}_\mu$. Moreover we will define an action of $\mathbb{C}^\times$ on $\mathfrak{M}$ covering the standard action on $\mathbb{C}$ such that $\mathfrak{M}^{\mathbb{C}^\times}$ is projective and the limit point $\lim_{\lambda \to 0} \lambda x$ exists for all $x \in \mathfrak{M}$. Then Proposition 7.2.1 will prove that $H^*(\mathcal{Q}_\mu)$ has pure mixed Hodge structure.

Similarly to (2.2.5) we define

$$\begin{array}{rcl} \mu : \mathrm{Rep}_{\mathbb{K}}(\overline{\Gamma}, \mathbf{v}) \times \mathbb{C} & \to & M(\mathbf{v}, \mathbb{K})^0 \\ \left((x_\gamma)_{\gamma \in \overline{\Omega}}, z\right) & \mapsto & \sum_{\gamma \in \Omega} [x_\gamma, x_\gamma^*] - \sum_{i \in I} z\xi_i \mathrm{Id}. \end{array}$$

Now for $\mathbf{n} = (n_i)_{i \in I} \in \mathbb{Z}^I$ satisfying $\sum_{i \in I} n_i v_i = 0$ we have a character $\chi_{\mathbf{n}}$ of $\mathrm{G}_{\mathbf{v}}$ given by

$$\chi_{\mathbf{n}}((g_i)_{i \in I}) = \prod_{i \in I} \det(g_i)^{n_i}.$$

We call

$$\mathbf{n} = (n_i)_{i \in I} \in \mathbb{Z}^I \textit{ generic} \text{ if for } \mathbf{v}' \in \mathbb{Z}^I_{\geq 0} \text{ such that } 0 < \mathbf{v}' < \mathbf{v} \text{ implies that } \mathbf{n} \cdot \mathbf{v}' \neq 0. \tag{2.2.8}$$

Because $\boldsymbol{\mu}$ is indivisible we can take a generic $\mathbf{n}$. Now the character $\chi_{\mathbf{n}}$ will give a linearization of the action of $\mathrm{G}_{\mathbf{v}}$ on $\mu^{-1}(0) \times \mathbb{C}$ and so we can consider the GIT quotient

$$\mathfrak{M} := \mu^{-1}(0) /\!/_{\chi_{\mathbf{n}}} \mathrm{G}_{\mathbf{v}}.$$

We note that $\mathbb{C}^\times$ acts on $\mu^{-1}(0)$ by

$$\lambda \left((x_\gamma)_{\gamma \in \overline{\Omega}}, z\right) = \left((\lambda x_\gamma)_{\gamma \in \overline{\Omega}}, \lambda^2 z\right) \tag{2.2.9}$$

commuting with the $\mathrm{G}_{\mathbf{v}}$ action thus descends to an action of $\mathbb{C}^\times$ on $\mathfrak{M}$. Finally, we also have the map $f : \mathfrak{M} \to \mathbb{C}$ given by $f((x_\gamma)_{\gamma \in \overline{\Omega}}, z) = z$. We have

**Theorem 2.2.7.** *For a generic* $\mathbf{n}$ *the variety $\mathfrak{M}$ is non-singular, $f$ is a smooth map (in other words a submersion), $\mathfrak{M}^{\mathbb{C}^\times}$ is complete and* $\lim_{\lambda \to 0} \lambda x$ *exists for all $x \in \mathfrak{M}$.*

*Proof.* $\mathfrak{M}$ is non-singular because by the Hilbert-Mumford criterion for (semi)-stability [22], every semi-stable point on $\mu^{-1}(0)$ will be stable due to (2.2.8).

The map $f$ is a submersion because the derivative $\partial_z \mu = \sum_{i \in I} \xi_i \mathrm{Id} \neq 0$ is non-zero.

Construct the affine GIT quotient

$$\mathfrak{M}_0 := \mu^{-1}(0) /\!/_{\chi_{\mathbf{0}}} \mathrm{G}_{\mathbf{v}}$$

using the non-generic $\mathbf{0} \in \mathbb{Z}^I$ weight. Then the natural map $\mathfrak{M} \to \mathfrak{M}_0$ is proper and the $\mathbb{C}^\times$-action (2.2.9) on $\mathfrak{M}_0$ has one fixed point coming from the origin in $\mathrm{Rep}_{\mathbb{K}}(\overline{\Gamma}, \mathbf{v}) \times \mathbb{C}$ and all $\mathbb{C}^\times$ orbits on $\mathfrak{M}_0$ will have this origin in its closure. The remaining statements of the Proposition follow. □

To conclude the proof of Proposition 2.2.6 it is enough to note that by the GIT construction we have the natural map $f^{-1}(1) \to \mathfrak{M}_\xi$, which - as a resolution of singularities and $\mathfrak{M}_\xi$ being non-singular - is an isomorphism. Therefore Proposition 7.2.1 implies the result. □

## 2.3 Generating functions

We denote by $\mathcal{P}$ the set of all partitions including the unique partition 0 of 0, by $\mathcal{P}^*$ the set of non-zero partitions and by $\mathcal{P}_n$ be the set of partitions of $n$. Partitions $\lambda$ are denoted by $\lambda = (\lambda_1, \lambda_2, \ldots)$, where $\lambda_1 \geq \lambda_2 \geq \ldots \geq 0$. We will also sometimes write a partition as $(1^{m_1}, 2^{m_2}, \ldots, n^{m_n})$ where $m_i$ denotes the multiplicity of $i$ in $\lambda$. The *size* of $\lambda$ is $|\lambda| := \sum_i \lambda_i$; the *length* $l(\lambda)$ of $\lambda$ is the maximum $i$ with $\lambda_i > 0$.

We choose once for all a total order $\geq$ on the set of pairs $(d, \lambda)$ where $d \in \mathbb{Z}^*_{\geq 0}$ and $\lambda \in \mathcal{P}^* = \mathcal{P} - \{0\}$ such that if $d > d'$ then $(d, \lambda) > (d', \mu)$, if $|\lambda| > |\mu|$ then $(d, \lambda) > (d, \mu)$, and if $|\lambda| = |\mu|$, then $(d, \lambda) \geq (d, \mu)$ if $\lambda$ is larger than $\mu$ with respect to the lexicographic order. We denote by $\mathbf{T}$ the set of non-increasing sequences $\omega = (d_1, \lambda^1) \geq (d_2, \lambda^2) \geq \ldots \geq (d_r, \lambda^r)$, which we will call a *type*. The *size* of a type $\omega$ is $|\omega| := \sum_i d_i |\lambda^i|$. We denote by $\mathbf{T}_n$ the the types of size $n$. We denote by $m_{d,\lambda}(\omega)$ the multiplicity of $(d, \lambda)$ in $\omega$. As with partitions it is sometimes convenient to consider a type as a collection of integers $m_{d,\lambda} \geq 0$ indexed by pairs $(d, \lambda) \in \mathbb{Z}_{>0} \times \mathcal{P}^*$.

Let $\Lambda(\mathbf{x}_1, \ldots, \mathbf{x}_k) := \Lambda(\mathbf{x}_1) \otimes_{\mathbb{Z}} \cdots \otimes_{\mathbb{Z}} \Lambda(\mathbf{x}_k)$ be the ring of functions separately symmetric in each set $\mathbf{x}_1, \mathbf{x}_2, \ldots, \mathbf{x}_k$ of infinitely many variables. Depending on the situation we will consider elements in $\Lambda(\mathbf{x}_1, \ldots, \mathbf{x}_k) \otimes_{\mathbb{Z}} \mathbb{Q}(q, t)$ where $q$ and $t$ are two indeterminates or similarly $\Lambda(\mathbf{x}_1, \ldots, \mathbf{x}_k) \otimes_{\mathbb{Z}} \mathbb{Q}(z, w)$ . To ease the notation we will simply write $\Lambda$ for the various rings $\Lambda(\mathbf{x}), \Lambda(\mathbf{x}_1, \ldots, \mathbf{x}_k), \Lambda(\mathbf{x}_1, \ldots, \mathbf{x}_k) \otimes_{\mathbb{Z}} \mathbb{Q}(q, t), \Lambda(\mathbf{x}_1, \ldots, \mathbf{x}_k) \otimes_{\mathbb{Z}} \mathbb{Q}(z, w)$, etc. as long as the context is clear. When considering elements $a_{\boldsymbol{\mu}} \in \Lambda$ indexed by multipartitions $\boldsymbol{\mu} = (\mu^1, \ldots, \mu^r) \in \mathcal{P}^k$, we will always assume that they are homogeneous of degree $(|\mu^1|, \ldots, |\mu^k|)$. Given any family of symmetric functions indexed by partitions $\mu \in \mathcal{P}$ and a multipartition $\boldsymbol{\mu} \in \mathcal{P}^k$ as above define

$$a_{\boldsymbol{\mu}} := a_{\mu^1}(\mathbf{x}_1) \cdots a_{\mu^k}(\mathbf{x}_k).$$

Let $\langle \cdot, \cdot \rangle$ be the Hall pairing on $\Lambda(\mathbf{x})$, extend its definition to $\Lambda(\mathbf{x}_1, \ldots, \mathbf{x}_k)$ by setting

$$\langle a_1(\mathbf{x}_1) \cdots a_k(\mathbf{x}_k), b_1(\mathbf{x}_1) \cdots b_k(\mathbf{x}_k) \rangle = \langle a_1, b_1 \rangle \cdots \langle a_k, b_k \rangle, \tag{2.3.1}$$

for any $a_1, \ldots, a_k; b_1, \ldots, b_k \in \Lambda(\mathbf{x})$ and to formal series by linearity.

Given any family of symmetric functions $A_\lambda(\mathbf{x}_1, \ldots, \mathbf{x}_k; q, t) \in \Lambda$ indexed by partitions with $A_0 = 1$, we extend its definition to types $\omega = (d_1, \omega^1)(d_2, \omega^2) \ldots (d_r, \omega^r) \in \mathbf{T}$ by setting

$$A_\omega(\mathbf{x}_1, \ldots, \mathbf{x}_k; q, t) := \prod_j A_{\omega^j}(\mathbf{x}_1^{d_j}, \ldots, \mathbf{x}_k^{d_j}; q^{d_j}, t^{d_j}).$$

Here $\mathbf{x}^d$ stands for all the variables $x_1, x_2, \ldots$ in $\mathbf{x}$ replaced by $x_1^d, x_2^d, \ldots$ (technically we are applying the Adams operation $\psi_d$ to $A_{\omega^j}$ in the $\lambda$-ring $\Lambda$).

We will use the maps Exp and Log of [17] extended to $\Lambda$. The general context is that of $\lambda$-rings [9] but the following discussion will suffice for us. For $V \in T\Lambda[[T]]$ let

$$\mathrm{Exp} : T\Lambda[[T]] \longrightarrow 1 + T\Lambda[[T]] \tag{2.3.2}$$

$$V \mapsto \exp\left( \sum_{d \geq 1} \tfrac{1}{d} V(\mathbf{x}_1^d, \ldots, \mathbf{x}_k^d, q^d, t^d, T^d) \right). \tag{2.3.3}$$

The map Exp is related to the Cauchy kernel

$$C(\mathbf{x}) := \prod_i (1 - x_i)^{-1}$$

by

$$\mathrm{Exp}(X) = C(\mathbf{x}), \qquad X := x_1 + x_2 + \cdots = m_{(1)}(\mathbf{x}),$$

($m_\lambda(\mathbf{x}) \in \Lambda(\mathbf{x})$ is the monomial symmetric function). It has an inverse Log defined as follows. Given $F \in 1 + T\Lambda[[T]]$ let $U_n \in \Lambda$ be the coefficients in the expansion

$$\log(F) =: \sum_{n \geq 1} U_n(\mathbf{x}_1, \ldots, \mathbf{x}_k; q, t) \frac{T^n}{n}.$$

Define

$$V_n(\mathbf{x}_1,\ldots,\mathbf{x}_k;q,t) := \frac{1}{n}\sum_{d|n}\mu(d)\,U_{n/d}(\mathbf{x}_1^d,\ldots,\mathbf{x}_k^d;q^d,t^d), \tag{2.3.4}$$

where $\mu$ is the ordinary Möbius function, then

$$\mathrm{Log}(F) := \sum_{n\geq 1} V_n(\mathbf{x}_1,\ldots,\mathbf{x}_k;q,t)\,T^n.$$

Suppose $A_\lambda(\mathbf{x}_1,\ldots,\mathbf{x}_k;q,t)\in\Lambda$ is a sequence of symmetric functions indexed by partitions with $A_0 = 1$. We want an expression for $V_n\in\Lambda$ in

$$\sum_{n\geq 1} V_n T^n := \mathrm{Log}\left(\sum_{\lambda\in\mathcal{P}} A_\lambda T^{|\lambda|}\right).$$

We first compute

$$\sum_{n\geq 1} U_n \frac{T^n}{n} := \log\left(\sum_{\lambda\in\mathcal{P}} A_\lambda T^{|\lambda|}\right),$$

where $U_n$ and $V_n$ are related by (2.3.4). By the multinomial theorem we have

$$\frac{U_n}{n} = \sum_{m_\lambda}(-1)^{m-1}(m-1)!\prod_\lambda \frac{A_\lambda^{m_\lambda}}{m_\lambda!}, \tag{2.3.5}$$

where $m := \sum_\lambda m_\lambda$ and the sum is over all sequences $\{m_\lambda\}$ of non-negative integers such that

$$\sum_\lambda m_\lambda|\lambda| = n.$$

We find then

$$V_n = \sum \frac{\mu(d)}{d}(-1)^{m_d-1}(m_d-1)!\prod_\lambda \frac{A_\lambda(\mathbf{x}_1^d,\ldots,\mathbf{x}_k^d;q^d,t^d)^{m_{d,\lambda}}}{m_{d,\lambda}!},$$

where the sum is over all sequences of non-negative integers $m_{d,\lambda}$ indexed by pairs $(d,\lambda)\in\mathbb{Z}_{>0}\times\ \mathcal{P}^*$ satisfying

$$\sum_\lambda m_{d,\lambda} d|\lambda| = n$$

and

$$m_d := \sum_\lambda m_{d,\lambda}.$$

Alternatively, we may consider not collecting equal terms when expanding the logarithm to obtain

$$V_n = \sum \frac{\mu(d)}{d}\frac{(-1)^{r-1}}{r}A_{\lambda^1}(q^d)\cdots A_{\lambda^r}(q^d), \tag{2.3.6}$$

where the sum is over $\lambda^1,\lambda^2,\ldots\in\mathcal{P}^*$ and $d\in\mathbb{Z}_{>0}$ such that

$$n = d\sum_j |\lambda^j|.$$

Finally, we may also rewrite the expression for $V_n$ as a sum over types $\omega$:

$$V_n = \sum_{|\omega|=n} C_\omega^0 A_\omega, \tag{2.3.7}$$

so that

$$\mathrm{Log}\left(\sum_{\lambda\in\mathcal{P}} A_\lambda T^{|\lambda|}\right) = \sum_\omega C_\omega^0 A_\omega\ T^{|\omega|}, \tag{2.3.8}$$

where $C^0_\omega = 0$ unless $\omega$ is concentrated in some degree $d$; i.e., $\omega = (d,\omega^1)(d,\omega^2)\cdots(d,\omega^r)$, in which case,

$$C^0_\omega = \frac{\mu(d)}{d}(-1)^{r-1}\frac{(r-1)!}{\prod_\lambda m_{d,\lambda}(\omega)!}. \tag{2.3.9}$$

*Remark* 2.3.1. The formal power series $\sum_{n\geq 0} a_n T^n$ with $a_n \in \Lambda$ that we will consider in what follows will all have $a_n$ homogeneous of degree $n$. Hence we will typically scale the variables of $\Lambda$ by $1/T$ and eliminate $T$ altogether.

## 2.4 The genus $g$ hook function

For details on this section we refer the reader to [17]. Given a partition $\lambda \in \mathcal{P}_n$ we define the genus $g$ *hook function* $\mathcal{H}^g_\lambda(z,w)$ by

$$\mathcal{H}^g_\lambda(z,w) := \prod_{s\in\lambda}\frac{(z^{2a(s)+1}-w^{2l(s)+1})^{2g}}{(z^{2a(s)+2}-w^{2l(s)})(z^{2a(s)}-w^{2l(s)+2})},$$

where the product is over all cells $s$ of $\lambda$ with $a(s)$ and $l(s)$ its arm and leg length, respectively.

We will use the following specializations:

1) Let $\lambda = (1^{m_1}, 2^{m_2}, \ldots) = (\lambda_1, \lambda_2, \ldots, \lambda_r) \in \mathcal{P}_n$,

$$\begin{aligned}\mathcal{H}^g_\lambda(0,\sqrt{q}) &= \prod_{a=0}\frac{q^{g(2l+1)}}{q^l(q^{l+1}-1)}\prod_{a\neq 0} q^{(g-1)(2l+1)}\\ &= \frac{q^{(g-1)(2n(\lambda)+|\lambda|)}}{\prod_{i\geq 1}(1-1/q)(1-1/q^2)\ldots(1-1/q^{m_i})} = \frac{q^{(g-1)\langle\lambda,\lambda\rangle}}{b_\lambda(1/q)} = \frac{q^{g\langle\lambda,\lambda\rangle}}{a_\lambda(q)}\end{aligned}$$

where $a_\lambda(q)$ is the cardinality of the centralizer of a unipotent element of $\mathrm{GL}_n(\mathbb{F}_q)$ with Jordan form of type $\lambda$ [32, IV, (2.7)].

2) It is also not difficult to verify that

$$\begin{aligned}\mathcal{H}^g_\lambda(\sqrt{q}, 1/\sqrt{q}) &= \left(q^{-\frac{1}{2}\sum_z 2l(z)+1} H_\lambda(q)\right)^{2g-2}\\ &= \left(q^{-\frac{1}{2}\langle\lambda,\lambda\rangle} H_\lambda(q)\right)^{2g-2}\end{aligned}$$

where

$$H_\lambda(q) := \prod_{s\in\lambda}(1-q^{h(s)}),$$

is the *hook polynomial* [32, I, 3, example 2].

## 2.5 Mixed Hodge polynomials and polynomial count varieties

We refer the reader to [17] for details on this section. For a complex quasi-projective algebraic variety $X$ we let $H(X;x,y,z)$ and $H_c(X;x,y,z)$ be its mixed Hodge polynomial and compactly supported mixed Hodge polynomial, respectively. They satisfy the following properties. The specialization $H(X;1,1,z)$ is the Poincaré polynomial $P(X;z) := \sum_k \dim H^k(X,\mathbb{C})\, z^k$ and similarly with $H_c$ and $P_c$. The $E$-polynomial of $X$ is $E(X;x,y) = H_c(X;x,y,-1) = \sum_{i,j,k}(-1)^k h_c^{i,j;k}(X)\, x^i y^j$. The value $E(X;1,1)$ is the compact Euler characteristic $\sum_i (-1)^i \dim H^i_c(X,\mathbb{C})$, which is equal to the ordinary Euler characteristic by [19]. We denote it by $E(X)$.

If $X$ is non-singular of pure dimension $d$, i.e., if $X$ is the disjoint union of its irreducible components all non-singular of same dimension $d$, then Poincaré duality implies that

$$h_c^{d-i,d-j;2d-k}(X) = h^{i,j;k}(X), \qquad \text{all } i, j, k,$$

or, equivalently,

$$H_c(X;x,y,t) = (xyt^2)^d H(X;x^{-1},y^{-1},t^{-1}). \tag{2.5.1}$$

We recall the result of Katz given in the appendix to [17].

**Theorem 2.5.1.** *Assume that $X/\mathbb{C}$ is strongly-polynomial count with counting polynomial $P_X \in \mathbb{Z}[t]$. Then*

$$E(X;x,y) = P_X(xy).$$

If $X$ is polynomial-count, we put $E(X;q) := E(X;\sqrt{q},\sqrt{q})$ and just call it the $E$-polynomial of $X$ to simplify. Note that in this case $\sum_k (-1)^k h_c^{i,j;k}(X) = 0$ if $i \neq j$.

**Proposition 2.5.2.** *Assume that $X$ is polynomial-count and that the mixed Hodge structure on the compactly supported cohomology $H_c^*(X)$ is pure then*

$$E(X;q) = P_c(X;\sqrt{q}).$$

*Proof.* By the above remark we have $\sum_k (-1)^k h_c^{i,j;k}(X) = 0$ if $i \neq j$. Since the only non-zero term of this sum is when $k = i + j$, by the purity assumption, we get that $(-1)^{i+j} h_c^{i,j;i+j}(X) = 0$ if $i \neq j$. Hence the non-zero mixed Hodge numbers are all of the form $h_c^{i,i;2i}(X)$ and $E(X;q) = \sum_i h_c^{i,i;2i}(X) q^i$. □

## 2.6 Complex characters of $\mathrm{GL}_n(\mathbb{F}_q)$ and $\mathfrak{gl}_n(\mathbb{F}_q)$

Here we recall how to construct the irreducible characters of $\mathrm{GL}_n(\mathbb{F}_q)$ and $\mathfrak{gl}_n(\mathbb{F}_q)$ using the Deligne-Lusztig theory. We choose a prime $\ell$ which is invertible in the finite field $\mathbb{F}_q$. Since Deligne-Lusztig theory uses $\ell$-adic cohomology it will be more convenient to work with $\overline{\mathbb{Q}}_\ell$-characters instead of complex characters. Note that there is a non-canonical isomorphism over $\mathbb{Q}$ between the two fields $\mathbb{C}$ and $\overline{\mathbb{Q}}_\ell$. The counting formulas (1.2.1) and (1.3.2), which involve character values, do not depend on the choice of such an isomorphism.

**2.6.1. Generalities** Let $n \in \mathbb{Z}_{>0}$, we put $\mathrm{GL}_n = \mathrm{GL}_n(\overline{\mathbb{F}}_q)$, and $\mathfrak{gl}_n = \mathfrak{gl}_n(\overline{\mathbb{F}}_q)$. Unless specified, here the letter $G$ will always denote a Levi subgroup of a parabolic subgroup of $\mathrm{GL}_n$, i.e., a subgroup of $\mathrm{GL}_n$ which is $\mathrm{GL}_n$-conjugate to some $H = \prod_{i=1}^r \mathrm{GL}_{n_i}$ where $\sum_{i=1}^r n_i = n$. For short we will say that $G$ is a *Levi subgroup* of $\mathrm{GL}_n$. If $n_i = 1$ for all $i$, then $G$ is a maximal torus of $\mathrm{GL}_n$. The Lie algebra of $G$ is isomorphic to the Lie algebra $\mathcal{H} = \bigoplus_i \mathfrak{gl}_{n_i}$ of $H$. Let $\mathrm{Ad} : G \to \mathrm{GL}(\mathfrak{g})$ be the adjoint representation: we have $\mathrm{Ad}(g)x = gxg^{-1}$ for $g \in G$ and $x \in \mathfrak{g}$. For $g \in G$, we denote by $g_s$ the semisimple part of $g$ and by $g_u$ the unipotent part of $g$, we have $g = g_s g_u = g_u g_s$. If $x \in \mathfrak{g}$, we denote respectively by $x_s$ and $x_n$ the semi-simple part of $x$ and the nilpotent part of $x$. We then have $x = x_s + x_n$ with $[x_s, x_n] = 0$. Let $x \in \mathfrak{g}$ and let $K$ be a subgroup of $G$, we denote by $C_K(x)$ the centralizer of $x$ in $K$ with respect to the adjoint action. If $\mathfrak{k}$ is a Lie subalgebra of $\mathfrak{g}$, we denote by $C_\mathfrak{k}(x)$ the centralizer of $x$ in $\mathfrak{k}$, i.e., $C_\mathfrak{k}(x) = \{y \in \mathfrak{k} \mid [x,y] = 0\}$. We denote respectively by $Z_G$ the center of $G$ and by $z(\mathfrak{g})$ the center of $\mathfrak{g}$. If $L$ is a Levi subgroup of $G$ (i.e., a Levi subgroup of $\mathrm{GL}_n$ which is contained in $G$), then we denote by $W_G(L)$ the finite group $N_G(L)/L$ where $N_G(L)$ denotes the normalizer of $L$ in $G$.

Finally, we denote by $G_{\mathrm{uni}}$, resp. $\mathfrak{g}_{\mathrm{nil}}$, the subvariety of unipotent elements of $G$, resp. the subvariety of nilpotent elements of $\mathfrak{g}$.

**2.6.2. Frobenius endomorphisms:** We denote by $F : \mathrm{GL}_n \to \mathrm{GL}_n$, and $F : \mathfrak{gl}_n \to \mathfrak{gl}_n$ the *standard* Frobenius endomorphisms $(a_{ij}) \mapsto (a_{ij}^q)$. Assume that $G$ is $F$-stable. Then $\mathfrak{g} \subset \mathfrak{gl}_n$ is $F$-stable and the restrictions $F : G \to G$, $F : \mathfrak{g} \to \mathfrak{g}$ are Frobenius endomorphisms on $G$ and $\mathfrak{g}$. We also have $F(\mathrm{Ad}(g)x) = \mathrm{Ad}(F(g))F(x)$, therefore, Ad induces an action of the finite group $G^F$ on the finite Lie algebras $\mathfrak{g}^F$. Since $G$ is conjugate to $H$, the Frobenius endomorphism $F : G \to G$ corresponds to some $F' : H \to H$ which we write $(G,F) \simeq (H,F')$. We then have $G^F \simeq H^{F'}$. The Frobenius endomorphism $F'$ is of the form $wF : H \to H$, $h \mapsto wF(h)w^{-1}$ for some $w \in N_{\mathrm{GL}_n}(H)$. We say that an $F$-stable maximal torus $T \subset G$ of rank $n$ is *split* if there exists an isomorphism $T \simeq (\overline{\mathbb{F}}_q^\times)^n$ defined over $\mathbb{F}_q$. The $\mathbb{F}_q$-*rank* of an $F$-stable maximal torus of $G$ is defined to be the rank of its maximal split subtori. An $F$-stable maximal torus of $G$

is said to be $G$-*split* if it is maximally split in $G$. The $G$-split $F$-stable maximal tori of $G$ are those which are contained in some $F$-stable Borel subgroup of $G$.

**2.6.3.** ***F*-conjugacy classes:** Let $T$ be an $F$-stable maximal torus of $G$. The Frobenius $F$ acts on the finite group $W_G(T)$ and we say that two elements $w, v \in W_G(T)$ are $F$-conjugate if there exists $h \in W_G(T)$ such that $w = hv(F(h))^{-1}$. Then we can parametrize the $G^F$-conjugacy classes of the $F$-stable maximal tori of $G$ by the $F$-conjugacy classes of $W_G(T)$ as follows. Let $T'$ be an $F$-stable maximal torus of $G$. Then there exists $g \in G$ such that $T' = gTg^{-1}$, i.e., $g^{-1}F(g) \in N_G(T)$. There is a well-defined map which sends the $G^F$-conjugacy class of $T'$ to the $F$-conjugacy class of the image $w$ of $g^{-1}F(g)$ in $W_G(T)$, moreover this map is bijective. This parametrization depends only on the $G^F$-conjugacy class of $T$. If $w \in W_G(T)$, then we will denote by $T_w$ an arbitrary $F$-stable maximal torus of $G$ which is in the $G^F$-conjugacy class corresponding to the $F$-conjugacy class of $w$ in $W_G(T)$, and we will denote by $\mathfrak{t}_w$ its Lie algebra. Under the isomorphism $T \to T'$, $h \mapsto ghg^{-1}$, the Frobenius $F : T' \to T'$ corresponds to $F' = wF : T \to T, h \mapsto \dot{w}F(h)\dot{w}^{-1}$ where $w$ is the image in $W_G(T)$ of $\dot{w} := g^{-1}F(g) \in N_G(T)$.

Unless specified, we will always consider parameterizations with respect to $G$-split $F$-stable maximal tori of $G$, in which case we will write $W_G$ instead of $W_G(T)$

**Example:** Let $n = 2$, let $x \in \mathbb{F}_{q^2} - \mathbb{F}_q$, and let

$$T = \left\{ \begin{pmatrix} a & 0 \\ 0 & b \end{pmatrix} \middle| \, a, b \in \overline{\mathbb{F}}_q^\times \right\}, \qquad T' = \left\{ \frac{1}{x^q - x} \begin{pmatrix} ax^q - bx & -a + b \\ (a-b)xx^q & -ax^q + bx \end{pmatrix} \middle| \, a, b \in \overline{\mathbb{F}}_q^\times \right\}.$$

Then $T'$ is $F$-stable, $T' = gTg^{-1}$ where $g = \begin{pmatrix} 1 & 1 \\ x & x^q \end{pmatrix}$, and $g^{-1}F(g) = \sigma := \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$. Therefore, $(T', F) \simeq (T, \sigma F)$, and we have $T^F \simeq \mathbb{F}_q^\times \times \mathbb{F}_q^\times$ and $T'^F \simeq T^{\sigma F} \simeq \mathbb{F}_{q^2}^\times$. Since $|W_{\mathrm{GL}_2}(T)| = 2$, any $F$-stable maximal torus of $\mathrm{GL}_2$ is either $\mathrm{GL}_2^F$-conjugate to $T$ or $T'$.

**2.6.4. Lusztig induction:** Let $\ell \nmid q$ be a prime. Let $L$ be an $F$-stable Levi subgroup of a (possibly non $F$-stable) parabolic subgroup $P$ of $G$. Following [6][29] we construct a virtual $\overline{\mathbb{Q}}_\ell[G^F]$-module $R_L^G(M)$ for any $\overline{\mathbb{Q}}_\ell[L^F]$-module $M$ as follows. Let $U_P$ be the unipotent radical of $P$ and let $\mathcal{L}_G : G \to G, g \mapsto g^{-1}F(g)$ be the Lang map. The variety $\mathcal{L}_G^{-1}(U_P)$ is endowed with a left action of $G^F$ by left multiplication and with a right action of $L^F$ by right multiplication. These action induce actions on the $\ell$-adic cohomology $H_c^i(\mathcal{L}_G^{-1}(U_P), \overline{\mathbb{Q}}_\ell)$. The virtual $\overline{\mathbb{Q}}_\ell$-vector space $H_c^*(\mathcal{L}_G^{-1}(U_P)) := \sum_i (-1)^i H_c^i(\mathcal{L}_G^{-1}(U_P), \overline{\mathbb{Q}}_\ell)$ is thus a virtual $\overline{\mathbb{Q}}_\ell[G^F]$-module-$\overline{\mathbb{Q}}_\ell[L^F]$. We put $R_L^G(M) := H_c^*(\mathcal{L}_G^{-1}(U_P)) \otimes_{\overline{\mathbb{Q}}_\ell[L^F]} M$.

Let $C(G^F)$ be the $\overline{\mathbb{Q}}_\ell$-vector space of all functions $G^F \to \overline{\mathbb{Q}}_\ell$ with are constant on conjugacy classes of $G^F$. If $C$ is a conjugacy class of $G^F$ and $x \in C$, we denote either by $1_C$ or $1_x^{G^F}$ the characteristic function of $C$ that takes the value 1 on $C$ and 0 elsewhere.

The Lusztig functor $R_L^G$ defines a $\mathbb{Z}$-linear map $\mathbb{Z}(\mathrm{Irr}(L^F)) \to \mathbb{Z}(\mathrm{Irr}(G^F))$ which by linearity extension leads to the Deligne-Lusztig induction $R_L^G : C(L^F) \to C(G^F)$.

For an $F$-stable maximal torus $T$ of $G$, let $Q_T^G : G_{\mathrm{uni}}^F \to \overline{\mathbb{Q}}_\ell$ be the restriction to $G_{\mathrm{uni}}^F$ of the function $R_T^G(\mathrm{Id})$. The function $Q_T^G$ is called a *Green function* and its values are products of the Green polynomials defined in [32, III (7.8)]. The following formula [6, Theorem 4.2] reduces the computation of the values of $R_T^G(\theta)$ to the computation of Green polynomials.

$$R_T^G(\theta)(g) = |C_G(g_s)^F|^{-1} \sum_{\{h \in G^F \,|\, g_s \in hTh^{-1}\}} Q_{hTh^{-1}}^{C_G(g_s)}(g_u)\theta(h^{-1}g_s h) \tag{2.6.1}$$

where $\theta \in C(T^F)$, $g \in G^F$.

**2.6.5. Characters of** $\mathrm{GL}_n(\mathbb{F}_q)$**:** The character table of $\mathrm{GL}_n(\mathbb{F}_q)$ was first computed by Green [11]. Here we recall how to construct it from the point of view of Deligne-Lusztig theory [31].

Here we assume that $G = \mathrm{GL}_n$. Let $L$ be an $F$-stable Levi subgroup of $G$ and let $\varphi$ be an $F$-stable irreducible character of $W_L$. Then there is an extension $\tilde{\varphi}$ of $\varphi$ to the semi-direct product $W_L \rtimes \langle F\rangle$ such that the function $\mathcal{X}^L_\varphi : L^F \to \overline{\mathbb{Q}}_\ell$ defined by

$$\mathcal{X}^L_\varphi = |W_L|^{-1} \sum_{w\in W_L} \tilde{\varphi}(wF) R^L_{T_w}(\mathrm{Id}_{T_w})$$

is an irreducible character of $L^F$. The characters $\mathcal{X}^L_\varphi$ are called the *unipotent characters* of $L^F$.

For $g \in G^F$ and $\theta \in \mathrm{Irr}(L^F)$, let ${}^g\theta \in \mathrm{Irr}(gL^Fg^{-1})$ be defined by ${}^g\theta(glg^{-1}) = \theta(l)$. We say that a linear character $\theta : L^F \to \overline{\mathbb{Q}}_\ell^\times$ is *regular* if for $n \in N_{G^F}(L)$, we have ${}^n\theta = \theta$ only if $g \in L^F$. We denote by $\mathrm{Irr}_{\mathrm{reg}}(L^F)$ the set of regular linear characters of $L^F$. Put $\epsilon_L = (-1)^{\mathbb{F}_q-rank(L)}$. Then for $\theta^L \in \mathrm{Irr}_{\mathrm{reg}}(L^F)$, the virtual character

$$\mathcal{X} := \epsilon_G\epsilon_L R^G_L(\theta^L \cdot \mathcal{X}^L_\varphi) = \epsilon_G\epsilon_L|W_L|^{-1} \sum_{w\in W_L} \tilde{\varphi}(wF) R^G_{T_w}(\theta^{T_w}) \tag{2.6.2}$$

where $\theta^{T_w} := \theta^L|_{T_w}$, is an irreducible true character of $G^F$ and any irreducible character of $G^F$ is obtained in this way [31]. An irreducible character of $G^F$ is thus completely determined by the $G^F$-conjugacy class of a datum $(L, \theta^L, \varphi)$ with $L$ an $F$-stable Levi subgroup of $G$, $\theta^L \in \mathrm{Irr}_{\mathrm{reg}}(L^F)$ and $\varphi \in \mathrm{Irr}(W_L)^F$. The irreducible characters corresponding to the data $(L, \theta^L, 1)$ are called *semisimple* characters of $G^F$. This process of decomposing the irreducible characters is sometimes called *Lusztig-Jordan decomposition*. By analogy with Jordan decomposition of conjugacy classes, the *semisimple part* of $\mathcal{X}$ would be $\theta^L$ and the unipotent part would be $\mathcal{X}^L_\varphi$. It is indeed well-known that if $C$ is a conjugacy class of $G^F$, $x \in C$, $L = C_G(x_s)$, then $R^G_L(1^L_{x_s} * 1^L_{x_u}) = 1_C$ where $*$ is the usual convolution product on $C(G^F)$ defined by $(f * h)(g) = \sum_{y\in G^F} f(y)h(gy^{-1})$.

**2.6.6. Characters of** $\mathfrak{gl}_n(\mathbb{F}_q)$**:** The characters of $\mathfrak{gl}_n(\mathbb{F}_q)$ were first studied by Springer [35].

We denote by $\mathrm{Fun}(\mathfrak{g}^F)$ the $\overline{\mathbb{Q}}_\ell$-vector space of all functions $\mathfrak{g}^F \to \overline{\mathbb{Q}}_\ell$ and by $C(\mathfrak{g}^F)$ the subspace of all functions $f : \mathfrak{g}^F \to \overline{\mathbb{Q}}_\ell$ which are $G^F$-invariant, i.e., for any $h \in G^F$ and any $x \in \mathfrak{g}^F$, $f(\mathrm{Ad}(h)x) = f(x)$. If $\mathcal{O}$ is a $G^F$-orbit of $\mathfrak{g}^F$ and $\sigma \in \mathcal{O}$, then we denote either by $1_\mathcal{O}$ or $1^G_\sigma \in C(\mathfrak{g}^F)$ the characteristic function of $\mathcal{O}$, i.e., $1^G_\sigma(x) = 1$ if $x \in \mathcal{O}$ and $1^G_\sigma(x) = 0$ otherwise. We are interested in the characters (non-necessarily irreducible) of the abelian group $(\mathfrak{g}^F, +)$ which are $G^F$-invariant, i.e., which are in $C(\mathfrak{g}^F)$. We call them the *invariant characters* of $\mathfrak{g}^F$. We say that an invariant character of $\mathfrak{g}^F$ is *irreducible* if it can not be written as a sum of two invariant characters. We denote by $\mathrm{Irr}_{G^F}(\mathfrak{g}^F)$ the set of irreducible invariant characters of $\mathfrak{g}^F$. We now describe them in terms of Fourier transforms.

We fix once for all a non-trivial additive character $\Psi : \mathbb{F}_q \to \overline{\mathbb{Q}}_\ell^\times$ and we denote by $\mu : \mathfrak{g} \times \mathfrak{g} \to \overline{\mathbb{F}}_q$ the trace map $(a, b) \mapsto \mathrm{Trace}(ab)$. It is a non-degenerate $G$-invariant symmetric bilinear form defined over $\mathbb{F}_q$. We define the Fourier transform $\mathcal{F}^\mathfrak{g} : \mathrm{Fun}(\mathfrak{g}^F) \to \mathrm{Fun}(\mathfrak{g}^F)$ with respect to $(\Psi, \mu)$ by

$$\mathcal{F}^\mathfrak{g}(f)(x) = \sum_{y\in\mathfrak{g}^F} \Psi(\mu(x, y))\, f(y).$$

Note that for $\sigma, x \in \mathfrak{g}^F$,

$$\mathcal{F}^\mathfrak{g}(1^G_\sigma)(x) = \sum_{y\in\mathcal{O}^{G^F}_\sigma} \Psi(\mu(x, y)). \tag{2.6.3}$$

For a fixed $y \in \mathfrak{g}^F$, the map $\mathfrak{g}^F \to \overline{\mathbb{Q}}_\ell$, $x \mapsto \Psi(\langle x, y\rangle)$ is an irreducible characters of the abelian finite group $(\mathfrak{g}^F, +)$. Therefore $\mathcal{F}^\mathfrak{g}(1^G_\sigma)$, being a sum of characters of $(\mathfrak{g}^F, +)$, is a character of $(\mathfrak{g}^F, +)$. Since the sum is over a single adjoint orbit it is clearly an irreducible invariant character, i.e., $\mathcal{F}^\mathfrak{g}(1^G_\sigma) \in \mathrm{Irr}_{G^F}(\mathfrak{g}^F)$.

Let $L$ be an $F$-stable Levi subgroup of $G$ and let $\mathfrak{l}$ be its Lie algebra. We also have a Deligne-Lusztig induction $C(\mathfrak{l}^F) \to C(\mathfrak{g}^F)$ defined in [27]. Let $\omega : \mathfrak{g}_{\text{nil}} \to G_{\text{uni}}$ be the $G$-equivariant isomorphism given by $v \mapsto v + 1$. For an $F$-stable maximal torus $T$ of $G$ with $\mathfrak{t} := \text{Lie}(T)$, the Deligne-Lusztig induction $\mathcal{R}_{\mathfrak{t}}^{\mathfrak{g}}$ is defined by the following character formula:

$$\mathcal{R}_{\mathfrak{t}}^{\mathfrak{g}}(\theta)(x) = |C_G(x_s)^F|^{-1} \sum_{\{h \in G^F \mid x_s \in \text{Ad}(h)\mathfrak{t}\}} Q_{hTh^{-1}}^{C_G(x_s)}(\omega(x_n))\, \theta(\text{Ad}(h^{-1})x_s) \tag{2.6.4}$$

where $\theta \in C(\mathfrak{t}^F)$ and $x \in \mathfrak{g}^F$. Note that $C_G(x_s)$ is a Levi subgroup of $G$. For any semisimple element $\sigma \in \mathfrak{g}^F$, we have the following character formula [28, 7.3.3]:

$$\mathcal{F}^{\mathfrak{g}}(1_{\sigma}^{G}) = \epsilon_G \epsilon_L |W_L|^{-1} \sum_{w \in W_L} q^{d_L/2} \mathcal{R}_{\mathfrak{t}_w}^{\mathfrak{g}}(\mathcal{F}^{\mathfrak{t}_w}(1_{\sigma}^{T_w})) \tag{2.6.5}$$

where $L = C_G(\sigma)$, $d_L = \dim G - \dim L$.

Note that if $\mathcal{X}$ is a semisimple character of $\text{GL}_n(\mathbb{F}_q)$, then it is given by Formula (2.6.2) with $\tilde{\varphi} = 1$. Hence the character formulas for semisimple characters of $\text{GL}_n(\mathbb{F}_q)$ and $\mathfrak{gl}_n(\mathbb{F}_q)$ are similar and can be computed in the same way.

# 3 Counting with Fourier transforms

Let $K$ be an algebraically closed field isomorphic to $\mathbb{C}$. Fix such an isomorphism and pull back complex conjugation to $K$. This gives us an involution on $K$, which we denote by $x \mapsto \overline{x}$, such that $\overline{\zeta} = \zeta^{-1}$ for any root of unity $\zeta$ in $K$.

## 3.1 Group Fourier transform

Let $G$ be a finite group. We construct an analogue of the Fourier transform for class functions of $G$. For convenience we introduce the following notation. Let $G_\bullet$ be the measure space consisting of $G$ with its Haar measure, i.e., such that the measure of $\{g\}$ for $g \in G$ is $1/|G|$. Clearly, the total mass of $G_\bullet$ is 1. Let $C(G_\bullet)$ be the $K$-vector space of class functions on $G$ (a *class function* on $G$ is a function which is constant on conjugacy classes).

Similarly, let $G^\bullet$ be the measure space on the set of irreducible characters of $G$ with its Plancherel measure, i.e., such that the measure of the set $\{\chi\}$ for an irreducible character $\chi$ of $G$ is $\chi(1)^2/|G|$. Again, the total mass of $G^\bullet$ is 1. Let $C(G^\bullet)$ be the $K$-vector space of functions on $G^\bullet$.

We now define maps $\mathcal{F}_\bullet$ and $\mathcal{F}^\bullet$ which are analogues of the Fourier transform for $G$. We describe some of their formal properties leaving their proofs to the reader.

Define $\mathcal{F}_\bullet : C(G_\bullet) \to C(G^\bullet)$ by

$$\mathcal{F}_\bullet(f)(\chi) := |G| \int_{G_\bullet} f(g) \frac{\chi(g)}{\chi(1)}\, dg = \sum_g f(g) \frac{\chi(g)}{\chi(1)}$$

and $\mathcal{F}^\bullet : C(G^\bullet) \to C(G_\bullet)$ by

$$\mathcal{F}^\bullet(F)(g) := |G| \int_{G^\bullet} F(\chi) \overline{\left(\frac{\chi(g)}{\chi(1)}\right)} d\chi = \sum_\chi F(\chi)\chi(1)\overline{\chi}(g).$$

Up to a factor of $|G|$ these maps are mutual inverses of each other. More, precisely

$$\mathcal{F}^\bullet \circ \mathcal{F}_\bullet = |G| \cdot 1_{G_\bullet}, \qquad \mathcal{F}_\bullet \circ \mathcal{F}^\bullet = |G| \cdot 1_{G^\bullet}. \tag{3.1.1}$$

Consider the algebra structures on $C(G_\bullet)$ and $C(G^\bullet)$ defined by convolution and pointwise multiplication, respectively. I.e.,

$$(f_1 * f_2)(g) := \sum_{g_1 g_2 = g} f_1(g_1) f_2(g_2), \qquad f_1, f_2 \in C(G_\bullet)$$

and

$$(F_1 \cdot F_2)(\chi) := F_1(\chi) F_2(\chi), \qquad F_1, F_2 \in C(G^\bullet)$$

(it is easy to check that $f_1 * f_2$ is indeed a class function and hence belongs to $C(G_\bullet)$).

The maps $\mathcal{F}_\bullet$ and $\mathcal{F}^\bullet$ preserve these operations,

$$\mathcal{F}_\bullet(f_1) \cdot \mathcal{F}_\bullet(f_2) = \mathcal{F}_\bullet(f_1 * f_2), \qquad f_1, f_2 \in C(G_\bullet),$$

and

$$\mathcal{F}^\bullet(F_1) * \mathcal{F}^\bullet(F_2) = |G| \cdot \mathcal{F}^\bullet(F_1 \cdot F_2), \qquad F_1, F_2 \in C(G^\bullet).$$

**Proposition 3.1.1.** *For $f \in C(G_\bullet)$ we have*

$$f(1) = \int_{G^\bullet} \mathcal{F}_\bullet(f)(\chi)\, d\chi.$$

*Proof.* This is just a special case of Fourier inversion (3.1.1) as both sides equal $\mathcal{F}^\bullet(\mathcal{F}_\bullet(f))(1)$. □

Given a word $w \in F_r$, where $F_r = \langle X_1, \ldots, X_r \rangle$ is the free group in generators $X_1, \ldots, X_r$, we let $n(w)$ be the function on $G$ defined by

$$n(w)(z) := \#\{(x_1, \ldots, x_r) \in G^r \mid w(x_1, \ldots, x_r) = z\},$$

where $w(x_1, \ldots, x_r)$ is a shorthand for $\phi(w) \in G$ with $\phi : F_r \longrightarrow G$ the homomorphism mapping each $X_i$ to $x_i$.

Since $w(x_1, \ldots, x_r) = z$ implies $w(ux_1u^{-1}, \ldots, ux_ru^{-1}) = uzu^{-1}$ for any $u \in G$ it is clear that $n(w)$ is a class function. For convinience we define

$$N(w) := \mathcal{F}_\bullet(n(w)) \in C(G^\bullet).$$

The following lemma is straightforward and we omit its proof.

**Lemma 3.1.2.** *1) For a word $w \in F_r$*

$$n(w)(1) = \int_{G^\bullet} N(w)(\chi)\, d\chi$$

*2) If $w_1, w_2$ are two words in separate sets of variables then*

$$n(w_1 w_2) = n(w_1) * n(w_2).$$

*3) Let $C_1, \ldots, C_k$ be conjugacy classes in $G$ and $w \in F_r$. For $z \in G$ the number of solutions to*

$$w(x_1, \ldots, x_r) y_1 \cdots y_k = z, \qquad x_i \in G, y_j \in C_j$$

*is given by*

$$n(w) * 1_{C_1} * \cdots * 1_{C_k}(z),$$

*where for any conjugacy class $C$ we denote by $1_C \in C(G_\bullet)$ its characteristic function.*

A proof of the following result can be found in [17, 3.2].

**Lemma 3.1.3.** *For $w = X_1X_2X_1^{-1}X_2^{-1} \in F_2$ we have*

$$N(w)(\chi) = \left(\frac{|G|}{\chi(1)}\right)^2.$$

Finally, putting all the pieces together we see we have the following result.

**Proposition 3.1.4.** *Let $C_1, \ldots, C_k$ be conjugacy classes in $G$. The number of solutions to*

$$[x_1, y_1] \cdots [x_g, y_g] z_1 \cdots z_k = 1, \qquad x_i, y_i \in G, z_j \in C_j,$$

*equals*

$$\int_{G^\bullet} \mathcal{L}(\chi)^g \, f_\chi(C_1) \cdots f_\chi(C_k) \, d\chi,$$

*where*

$$\mathcal{L}(\chi) := \left(\frac{|G|}{\chi(1)}\right)^2$$

*and for any conjugacy class $C$*

$$f_\chi(C) := \mathcal{F}_\bullet(1_C)(\chi) = \frac{|C|\chi(C)}{\chi(1)}.$$

*Remark* 3.1.5. The proposition, as well as the introduction of the functions $f_\chi$, is due to Frobenius. Proofs can be found in many places in the literature since then. The purpose of reproving it here is to draw as close a parallel as possible with the additive version of the next section.

## 3.2 Equivariant Fourier Transform

If the group $G$ of the previous section is abelian what we have is the usual Fourier transform. Here we consider the situation of an abelian group, which will now denote by $A$, together with an action of another group $G$. We will describe a Fourier transform on $A$, which is equivariant with respect to the action of $G$ and parallels the one in § 3.1. We will apply this to our main example: $A = \mathfrak{gl}_n$ and $G = \mathrm{GL}_n$ acting via the adjoint action.

Let $A_\bullet$ be as in § 3.1 and let $X := \mathrm{Hom}(A, K^\times)$. We have a natural action of $G$ on $X$ as follows.

$$(g \cdot \phi)(a) := \phi(g^{-1} \cdot a).$$

Given a $G$-orbit $\mathcal{X}$ in $X$ we let

$$\chi := \sum_{\phi \in \mathcal{X}} \phi.$$

It is a $G$-invariant character of the group $A$. We let $A^\bullet$ be the measure space on the set of such $\chi$'s where the measure of $\{\chi\}$ is $\chi(0)/|A|$. The total measure of $A^\bullet$ is 1 as $\chi(0) = \#\mathcal{X}$.

In analogy with § 3.1 we let $C(A_\bullet)$ be the $K$-vector space of functions on $A$ which are $G$-invariant and let $C(A^\bullet)$ be the $K$-vector space of functions on $A^\bullet$.

Define $\mathcal{F}_\bullet : C(A_\bullet) \to C(A^\bullet)$ by

$$\mathcal{F}_\bullet(f)(\chi) := |A| \int_{A_\bullet} f(a) \frac{\chi(a)}{\chi(0)} \, da$$

and $\mathcal{F}^\bullet : C(A^\bullet) \to C(A_\bullet)$ by

$$\mathcal{F}^\bullet(F)(a) := |A| \int_{A^\bullet} F(\chi) \overline{\left(\frac{\chi(a)}{\chi(0)}\right)} d\chi.$$

Note that if $f : A \to K$ is constant on $G$-orbits and $\phi \in X$ then

$$\sum_{a \in A} f(a) \, \phi(a)$$

is constant on the $G$-orbit $\mathcal{X}$ of $\phi$. Hence we can write this sum as

$$\sum_{a\in A} f(a)\,\frac{\chi(a)}{\chi(0)},$$

where $\chi$ corresponds to $\mathcal{X}$. In other words, $\mathcal{F}_\bullet$ is (up to scaling) just the usual Fourier transform restricted to $G$-invariant functions on $A$. Similarly, $\mathcal{F}^\bullet$ is the usual inverse Fourier transform (up to scaling) restricted to $G$-stable characters of $A$. It follows that all the formal properties of the previous section also hold here. In particular, we have

**Proposition 3.2.1.** *For $f \in C(A_\bullet)$ we have*

$$f(0) = \int_{A^\bullet} \mathcal{F}_\bullet(f)(\chi)\, d\chi.$$

Now let $A = \mathfrak{gl}_n(\mathbb{F}_q)$ and $G = \mathrm{GL}_n(\mathbb{F}_q)$ acting via the adjoint action on $A$. We consider the additive analogue of Proposition 3.1.4. For $x, y \in A$ let $[x, y] := xy - yx$. For fixed $\phi \in X$ and $y \in A$ the map $x \mapsto \phi([x, y])$ is in $X$. Let $C_A(\phi)$ be the subgroup of $y \in A$ for which this character is trivial. Its cardinality only depends on the $G$-orbit $\mathcal{X}$ of $\phi$; we will denote it by $c(\chi)$, where $\chi = \sum_{\phi\in\mathcal{X}} \phi \in A^\bullet$ is associated to $\mathcal{X}$.

**Proposition 3.2.2.** *Let $O_1, \ldots, O_k$ be $G$-orbits in $A$. The number of solutions to*

$$[x_1, y_1] + \cdots + [x_g, y_g] + z_1 + \cdots + z_k = 0, \qquad x_i, y_i \in A, z_j \in O_j,$$

*equals*

$$\int_{A^\bullet} \mathcal{L}(\chi)^g\, f_\chi(O_1)\cdots f_\chi(O_k)\, d\chi,$$

*where*

$$\mathcal{L}(\chi) := |A|\, c(\chi)$$

*and and for any $G$-orbit $O$ in $A$*

$$f_\chi(O) := \mathcal{F}_\bullet(1_O)(\chi) = \frac{|O|\chi(O)}{\chi(0)}.$$

*Proof.* We may proceed exactly as with the proof of Proposition 3.1.4 thanks to the formal properties of the Fourier transform. The analogue of Lemma 3.1.3 is the following calculation. Let $n \in C(A_\bullet)$ be the function whose value at $a \in A$ is the number of solutions $x, y \in A$ of $[x, y] = a$. Then with our previous notation

$$\mathcal{F}_\bullet(n)(\chi) = \sum_{a\in A} n(a)\,\phi(a) = \sum_{x,y\in A} \phi([x, y]).$$

The sum $\sum_{x\in A} \phi([x, y])$ vanishes unless $y \in C_A(\phi)$ in which case it equals $|A|$. Hence $\mathcal{F}_\bullet(n)(\chi) = |A|\, c(\chi)$. □

*Remark* 3.2.3. With the notation of §2.6.6, the $\mathrm{GL}_n(\mathbb{F}_q)$-invariant characters of $\mathfrak{gl}_n(\mathbb{F}_q)$ are the functions $\mathcal{F}^{\mathfrak{g}}(1_O)$ where $O$ describes the set of adjoint orbits. Then note that

$$\mathcal{F}_\bullet(1_{O'})(\mathcal{F}^{\mathfrak{g}}(1_O)) = \mathcal{F}^{\mathfrak{g}}(1_{O'})(O).$$

and $c(\mathcal{F}^{\mathfrak{g}}(1_O)) = |\mathfrak{gl}_n(\mathbb{F}_q)| \cdot q^{\dim C_G(x)}$ where $x \in O$.

# 4 Sums of character values

In this section we obtain a formula which will be used, together with the results of §3, to compute the number of $\mathbb{F}_q$-rational points of character and quiver varieties over $\overline{\mathbb{F}}_q$. Here $G = \mathrm{GL}_n(\overline{\mathbb{F}}_q)$.

## 4.1 Types of conjugacy classes, irreducible characters and Levi subgroups

Let $C$ be a conjugacy classes of $G^F$. The Frobenius $f:\overline{\mathbb{F}}_q\rightarrow\overline{\mathbb{F}}_q, x\mapsto x^q$ acts on the set of eigenvalues of $C$, therefore we may write the set of eigenvalues of $C$ as a union of $\langle f\rangle$-orbits

$$\{\gamma_1,\gamma_1^q,...\}\coprod\{\gamma_1,\gamma_1^q,...\}\coprod ...\coprod\{\gamma_s,\gamma_s^q,...\}$$

Put $d_i=\#\{\gamma_i,\gamma_i^q,...\}$ and let $m_i$ be the multiplicity of $\gamma_i$. Clearly $\sum_i m_id_i=n$. The unipotent part of an element of $C$ defines a unique partition $\lambda^i$ of $m_i$ given by the Jordan blocks. Then $\lambda=(d_1,\lambda^1)...(d_s,\lambda^s)\in\mathbf{T}_n$ is called the *type* of $C$. Note that any type $\omega\in\mathbf{T}_n$ arises as the type of some conjugacy class of $G^F$. The types of the semisimple conjugacy classes are of the form $(d_1,1^{n_1})...(d_r,1^{n_r})$ where $n_1,...,n_r$ are the multiplicities of the eigenvalues and $1^{n_i}$ is the trivial partition $(1,...,1)$ of $n_i$.

Recall (see §2.6) that an irreducible character $\mathcal{X}$ of $G^F$ arises from a datum $(L,\theta^L,\varphi)$. There exists positive integers $d_i,n_i$, $i\in\{1,...,s\}$ such that

$$L\simeq\prod_{i=1}^s\mathrm{GL}_{n_i}(\overline{\mathbb{F}}_q)^{d_i}.$$

We choose the indexing such that $d_1\geq d_2,...\geq d_s$, and $n_i\geq n_j$ if $i>j$ and $d_i=d_j$. Let $\mathcal{S}_n$ be the symmetric group in $n$ letters and let $v\in\mathcal{S}_n\simeq W_G$, where $W_G$ is the Weyl group of $G$ (with respect to some split $F$-stable maximal torus), be such that the map $z\mapsto vzv^{-1}$ acts on each component of $\prod_{i=1}^s\mathrm{GL}_{n_i}(\overline{\mathbb{F}}_q)^{d_i}$ by circular permutation of the $d_i$ blocks of length $n_i$. Then

$$(L,F)\simeq\left(\prod_{i=1}^s\mathrm{GL}_{n_i}(\overline{\mathbb{F}}_q)^{d_i},vF\right)\tag{4.1.1}$$

and so $L^F$ is isomorphic to $\prod_{i=1}^s\mathrm{GL}_{n_i}(\mathbb{F}_{q^{d_i}})$. Moreover

$$(W_L,F)\simeq\left(\prod_{i=1}^s(\mathcal{S}_{n_i})^{d_i},v\right).$$

The $F$-conjugacy classes of $W_L$ are thus parametrized by the conjugacy classes of $\prod_i\mathcal{S}_{n_i}$, i.e., by the set $\mathcal{P}_{n_1}\times...\times\mathcal{P}_{n_s}$. The set of $F$-stable irreducible characters of $W_L$ is in bijection with $\mathrm{Irr}(\mathcal{S}_{n_1})\times...\times\mathrm{Irr}(\mathcal{S}_{n_s})$ which, by the Springer correspondence, is parametrized by $\mathcal{P}_{n_1}\times...\times\mathcal{P}_{n_s}$ in such a way that the trivial character corresponds to the multipartition $((n_1)^1,...,(n_s)^1)$. Hence $\varphi\in\mathrm{Irr}(W_L)^F$ defines a partition $\lambda^i\in\mathcal{P}_{n_i}$ for all $i\in\{1,...,s\}$. The type $(d_1,\lambda^1)(d_2,\lambda^2)...(d_s,\lambda^s)\in\mathbf{T}_n$ is called the *type* of the irreducible character $\mathcal{X}$ of $G^F$. Note that any type in $\mathbf{T}_n$ arises as the type of some irreducible character of $G^F$. The type of the semisimple irreducible characters of $G^F$ are of the form $(d_1,(n_1)^1)(d_2,(n_2)^2)...(d_s,(n_s)^s)$.

It will be convenient to introduce the set $\hat{\mathbf{T}}_n$ of non-increasing sequences $(d_1,n_1)...(d_r,n_r)$ with $d_i,n_i\in\mathbb{Z}_{>0}$ and $\sum_i d_in_i=n$ where $(d,k)>(d',k')$ if $d>d'$, or $d=d'$ and $k>k'$.

The types of the semisimple conjugacy classes are in bijection with $\hat{\mathbf{T}}_n$ by

$$(d_1,1^{n_1})...(d_r,1^{n_r})\mapsto(d_1,n_1)...(d_r,n_r).$$

Similarly $\hat{\mathbf{T}}_n$ parametrizes the types of the semisimple irreducible characters of $G^F$ by

$$(d_1,(n_1)^1)...(d_r,(n_r)^1)\mapsto(d_1,n_1)...(d_r,n_r).$$

The map which assigns to a semisimple element of $G$ the Levi subgroup $C_G(\sigma)$ gives a natural bijection between the types of the semisimple conjugacy classes of $G^F$ and the $G^F$-conjugacy classes of the $F$-stable Levi subgroups of $G$. We will use the set $\hat{\mathbf{T}}_n$ to parametrize the $G^F$-conjugacy classes of the $F$-stable Levi subgroups of $G$. Namely if $\lambda=(d_1,n_1)...(d_r,n_r)\in\hat{\mathbf{T}}_n$, then a representative $L$ of the corresponding $G^F$-conjugacy class will satisfy (4.1.1). In this case we say that $L$ is of *type* $\lambda$.

## 4.2 Generic characters and generic conjugacy classes

Let $L$ be an $F$-stable Levi subgroup of $G$. We say that a linear character $\Gamma$ of $Z_L^F$ is *generic* if its restriction to $Z_G^F$ is trivial and its restriction to $Z_M^F$ is non-trivial for any $F$-stable proper Levi subgroup $M$ of $G$ such that $L \subset M$. We put

$$(Z_L)_{\mathrm{reg}} := \{x \in Z_L | C_G(x) = L\}.$$

We have the following proposition.

**Proposition 4.2.1.** *Assume that $L$ is of type $\omega = (d_1, n_1)(d_2, n_2)...(d_r, n_r) \in \hat{\mathbf{T}}_n$ and that $\Gamma$ is a generic linear character of $Z_L^F$. Then*

$$\sum_{z \in (Z_L)^F_{\mathrm{reg}}} \Gamma(z) = (q-1)K^o_\omega$$

*with*

$$K^o_\omega = \begin{cases} (-1)^{r-1} d^{r-1} \mu(d)(r-1)! & \text{if } \forall i, d_i = d \\ 0 & \text{otherwise} \end{cases}$$

*where $\mu$ is the ordinary Möbius function.*

*Proof.* Let $\nu_\omega$ be an element of $\mathcal{S}_n$ such that the map $z \mapsto \nu_\omega z \nu_\omega^{-1}$ induces an action on each component of $M := \prod_i \mathrm{GL}_{n_i}(\overline{\mathbb{F}}_q)^{d_i}$ by circular permutation of the $d_i$ blocks of length $n_i$. Then $(L, F) \simeq (M, F_\omega)$ where $F_\omega$ is the Frobenius on $G$ defined by $F_\omega(g) = \nu_\omega F(g) \nu_\omega^{-1}$. Then the character $\Gamma$ can be transferred to a generic character $\Gamma_M$ of $Z_M^{F_\omega}$. Its restriction to $Z_G^{F_\omega}$ is also trivial. Then $\sum_{h \in (Z_M)^{F_\omega}_{\mathrm{reg}}} \Gamma_M(h) = \sum_{h \in (Z_L)^F_{\mathrm{reg}}} \Gamma(h)$. We denote by $P(\omega)$ the set of Levi subgroups $H$ of $G$ such that $M \subset H \subset G$ and $P(\omega)^{F_\omega}$ the elements of $P(\omega)$ fixed by $F_\omega$. We have the following partitions $Z_M = \coprod_{H \in P(\omega)} (Z_H)_{\mathrm{reg}}$. Indeed, if $z \in Z_M$, then $C_G(z)$ is a Levi subgroup $H$ of $G$ and clearly $z \in (Z_H)_{\mathrm{reg}}$. If $H \in P(\omega)$ then $F_\omega(H) \in P(\omega)$, and $(Z_H)_{\mathrm{reg}} \cap (Z_{F_\omega(H)})_{\mathrm{reg}} = \emptyset$ unless $H \in P(\omega)^{F_\omega}$. Therefore $F_\omega$ preserves the above partition, and $Z_M^{F_\omega} = \coprod_{H \in P(\omega)} (Z_H)^{F_\omega}_{\mathrm{reg}}$. We define a partial order on $P(\omega)$ by, $H_1 \leq H_2$ if $Z_{H_1} \subset Z_{H_2}$ (i.e. if $H_2 \subset H_1$). Then $G$ is the unique minimal element and $M$ is the unique maximal element. We have a map $\epsilon : P(\omega)^{F_\omega} \to \overline{\mathbb{Q}}_\ell$ that sends $H \in P(\omega)^{F_\omega}$ to $\sum_{z \in Z_H^{F_\omega}} \Gamma_M(z)$ and a map $\epsilon' : P(\omega)^{F_\omega} \to \overline{\mathbb{Q}}_\ell$ that sends $H \in P(\omega)^{F_\omega}$ to $\sum_{z \in (Z_H)^{F_\omega}_{\mathrm{reg}}} \Gamma_M(z)$. Since $Z_H^{F_\omega} = \coprod_{E \leq H} (Z_E)^{F_\omega}_{\mathrm{reg}}$ for all $H \in P(\omega)^{F_\omega}$, we have $\epsilon(H) = \sum_{E \leq H} \epsilon'(E)$ for all $H \in P(\omega)^{F_\omega}$. Then by inclusion-exclusion principle, we have $\epsilon'(H) = \sum_{E \leq H} \mu_\omega(E, H) \epsilon(E)$ for all $H \in P(\omega)^{F_\omega}$ where $\mu_\omega$ is the Möbius function on the poset $P(\omega)^{F_\omega}$. In particular

$$\sum_{z \in (Z_M)^{F_\omega}_{\mathrm{reg}}} \Gamma_M(z) = \sum_{H \leq M} \mu_\omega(H, M) \sum_{z \in Z_H^{F_\omega}} \Gamma_M(z).$$

Using the assumption on $\Gamma$, we deduce that

$$\sum_{z \in (Z_M)^{F_\omega}_{\mathrm{reg}}} \Gamma_M(z) = (q-1)\mu_\omega(G, M)$$

Let us compute $\mu_\omega(G, M)$. An element of $Z_M$ is a diagonal matrix $A \in \prod_{i=1}^r \mathrm{GL}_{n_i}(\overline{\mathbb{F}}_q)^{d_i}$ such that each component of $A$ in $\mathrm{GL}_{n_i}(\overline{\mathbb{F}}_q)$ is central. We identify $Z_M$ with $\prod_{i=1}^r (\overline{\mathbb{F}}_q^\times)^{d_i}$ in the obvious way. Then the elements of $(Z_M)_{\mathrm{reg}}$ correspond to the elements of the form $(a_{k,s})_{1 \leq k \leq r, 1 \leq s \leq d_k} \in \prod_{i=1}^r (\overline{\mathbb{F}}_q^\times)^{d_i}$ where $a_{i,j} \neq a_{k,l}$ if $(i, j) \neq (k, l)$. Let $I = \{i_{1,1}, ..., i_{1,d_1}, i_{2,1}, ..., i_{2,d_2}, ..., i_{r,1}, ..., i_{r,d_r}\}$ be a set whose elements are indexed by the pairs $(k, s)$ with $1 \leq k \leq r$ and $1 \leq s \leq d_k$. Then the partition $Z_M = \coprod_{H \in P(\omega)} (Z_H)_{\mathrm{reg}}$ is indexed by the partitions of the set $I$. The part $(Z_M)_{\mathrm{reg}}$ corresponds to the unique partition of $I$ which has $|I|$ parts, i.e. to $\{i_{1,1}\}, \{i_{1,2}\}, ..., \{i_{r,d_r}\}$, and the part $Z_G = (Z_G)_{\mathrm{reg}}$ which is the set of diagonal matrices with exactly one eigenvalue corresponds to the unique partition of $I$ which has one part. By abuse of notation we denote by $\nu_\omega \in \mathcal{S}_{|I|}$ the element which acts by circular permutation on each subset $\{i_{k,1}, ..., i_{k,d_k}\}$ of $I$. Then it induces an action on the set $P(I)$ of partitions of $I$ which corresponds via the bijection $P(I) \simeq P(\omega)$ to the action of

$F_\omega = \nu_\omega F$ on $P(\omega)$. We denote by $O$ the minimal element of $P(I)^{\nu_\omega}$ and by 1 the unique maximal element of $P(I)^{\nu_\omega}$. Then $\mu_\omega(G, M) = \mu'_\omega(0, 1)$ where $\mu'_\omega$ is the Möbius function on the poset $P(I)^{\nu_\omega}$. Now $\mu'_\omega(0, 1)$ was computed by Hanlon [12], and we find that $\mu'_\omega(0, 1) = K^o_\omega$. □

**Definition 4.2.2.** Let $\mathcal{X}_1, ..., \mathcal{X}_k$ be $k$-irreducible characters of $G^F$. For each $i$, let $(L_i, \theta_i, \varphi_i)$ be a datum defining $\mathcal{X}_i$. We say that the tuple $(\mathcal{X}_1, ..., \mathcal{X}_k)$ is *generic* if $\prod_{i=1}^k ({}^{g_i}\theta_i)|_{Z_M}$ is a generic character of $Z_M^F$ for any $F$-stable Levi subgroup $M$ of $G$ which satisfies the following condition: For all $i \in \{1, ..., k\}$, there exists $g_i \in G^F$ such that $Z_M \subset g_i L_i g_i^{-1}$.

Let $C_1, ..., C_k$ be $k$-conjugacy classes of $G^F$. For each $i \in \{1, ..., k\}$, let $s_i$ be the semisimple part of an element of $C_i$. Let $\tilde{\mathbf{C}}_i$ be the conjugacy class of $s_i$ in $G$. We say that $C_1, ..., C_k$ are generic if $\tilde{\mathbf{C}}_1, ..., \tilde{\mathbf{C}}_k$ are generic in the sense of Definition 2.1.1.

The following proposition is ”dual” to Proposition 4.2.1.

**Proposition 4.2.3.** *Let $C_1, ..., C_k$ be k-generic semisimple conjugacy classes of $G^F$, let $s_i \in C_i$ and put $L_i = C_G(s_i)$. Assume that M is an F-stable Levi subgroup of G of type $\omega \in \hat{\mathbf{T}}_n$ which satisfies the following condition: For all $i \in \{1, ..., k\}$ there exists $g_i \in G^F$ such that $Z_M \subset g_i L_i g_i^{-1}$. Then*

$$\sum_{\theta \in \mathrm{Irr}_{\mathrm{reg}}(M^F)} \prod_{i=1}^k \theta(g_i s_i g_i^{-1}) = (q-1) K^o_\omega.$$

Note that $g_i s_i g_i^{-1}$ is in the center of $g_i L_i g_i^{-1}$ and so commutes with the elements of $Z_M$, i.e., $g_i s_i g_i^{-1} \in C_G(Z_M) = M$. Therefore it makes sense to evaluate $\theta$ at $g_i s_i g_i^{-1}$ in the above formula.

## 4.3 Calculation of sums of character values

For a partition $\lambda$, let $t_\lambda \in \mathcal{S}_{|\lambda|}$ be an element in the conjugacy class of type $\lambda$. Then we denote by $z_\lambda$ the cardinality of the centralizer of $t_\lambda$ in $\mathcal{S}_{|\lambda|}$. For two partitions $\lambda, \mu$ such that $|\lambda| = |\mu|$, we denote by $\chi^\lambda_\mu$ the value at $t_\mu$ of the irreducible character $\chi^\lambda$ of $\mathcal{S}_{|\lambda|}$. We define the Green polynomial

$$Q^\tau_\lambda(q) = \sum_\nu \chi^\nu_\lambda \tilde{K}_{\nu\tau}(q) \tag{4.3.1}$$

where $\tilde{K}_{\nu\tau}(q)$ is the Kostka-Foulke polynomial [32, III, 7.11]. For a partition $\nu$, put $T_\nu := T_{t_\nu}$. If $u_\tau$ is a unipotent element of $G^F$ whose Jordan form is given by the partition $\tau$, then $Q^\tau_\nu(q)$ is the value $Q^G_{T_\nu}(u_\tau)$ of the Green function $Q^G_{T_\nu}$ of Deligne-Lusztig defined in §2.6.4.

Put $\hat{\mathbf{T}} = \cup_{n>0} \hat{\mathbf{T}}_n$, and define a map $\pi : \mathbf{T} \to \hat{\mathbf{T}}$ by

$$\pi((d_1, \omega^1)...(d_r, \omega^r)) = (d_1, |\omega^1|)...(d_r, |\omega^r|).$$

Write $\omega \sim \tau$ if $\pi(\omega) = \pi(\tau)$.

For two types $\omega$ and $\tau$, put
$\chi^\omega_\tau := \prod_i \chi^{\omega^i}_{\tau^i}$ if $\omega \sim \tau$, and $\chi^\omega_\tau = 0$ otherwise,
$Q^\omega_\tau(q) := \prod_i Q^{\omega^i}_{\tau^i}(q^{d_i})$ if $\omega \sim \tau$, and $Q^\omega_\tau(q) = 0$ otherwise,
$\tilde{K}_{\tau\omega}(q) := \prod_i \tilde{K}_{\tau^i\omega^i}(q^{d_i})$ if $\omega \sim \tau$, and $\tilde{K}_{\tau\omega}(q) = 0$ otherwise.

Note that Formula (4.3.1) extends to types, namely $Q^\omega_\tau(q) = \sum_\nu \chi^\nu_\tau \tilde{K}_{\nu\omega}(q)$ where $\tau, \omega, \nu \in \mathbf{T}$.

For $\tau=(d_1,\tau^1)(d_2,\tau^2)...(d_r,\tau^r)$, we put $[\tau]:=\cup_i d_i\cdot\tau^i$, where for a partition $\nu=(n_1,...,n_r)$ and $d\in\mathbb{Z}_{>0}$, $d\cdot\nu$ is the partition $(dn_1,...,dn_r)$, and where for partitions $\nu=(1^{n_1},2^{n_2},...)$ and $\mu=(1^{m_1},2^{m_2},...)$, the union $\nu\cup\mu$ is $(1^{n_1+m_1},2^{n_2+m_2},...)$.

For $\boldsymbol{\mu}=(\mu_1,...,\mu_k)\in(\mathbf{T}_n)^k$ and $\omega\in\mathbf{T}_n$, define

$$\mathbf{H}^{\boldsymbol{\mu}}_\omega(q):=\frac{(q-1)K^o_\omega}{|W(\omega)|}\prod_{i=1}^k(-1)^{n+f(\mu_i)}\sum_\tau\frac{z_{[\tau]}\chi^{\mu_i}_\tau}{z_\tau}\sum_{\{\nu|\,[\nu]=[\tau]\}}\frac{Q^\omega_\nu(q)}{z_\nu},$$

$$\hat{\mathbf{H}}^{\boldsymbol{\mu}}_\omega(q):=\frac{(q-1)K^o_\omega}{|W(\omega)|}\prod_{i=1}^k(-1)^{n+f(\omega)}\sum_\tau\frac{z_{[\tau]}\chi^{\omega}_\tau}{z_\tau}\sum_{\{\nu|\,[\nu]=[\tau]\}}\frac{Q^{\mu_i}_\nu(q)}{z_\nu}$$

where $K^o_\omega:=K^o_{\pi(\omega)}$, for any type $\tau=(d_1,\tau^1)...(d_r,\tau^r)$, $f(\tau):=\sum_j|\tau^j|$, and if we write $\omega=\{m_{d,\lambda}\}_{(d,\lambda)}$, then $W(\omega)=\prod_{(d,\lambda)\in\mathbb{Z}_{>0}\times\mathcal{P}^*}(\mathbb{Z}/d\mathbb{Z})^{m_{d,\lambda}}\times\mathcal{S}_{m_{d,\lambda}}$.

Let $(C_1,...,C_k)$ be $k$-generic conjugacy classes of $G^F$ of type $\boldsymbol{\mu}$ and let $(\mathcal{X}_1,...,\mathcal{X}_k)$ be $k$-generic irreducible characters of $G^F$ of type $\boldsymbol{\mu}$.

**Theorem 4.3.1.** *We have*
*(1)* $\sum_{\mathcal{X}}\prod_{i=1}^k\mathcal{X}(C_i)=\hat{\mathbf{H}}^{\boldsymbol{\mu}}_\omega(q)$ *where the sum is over the irreducible characters of* $G^F$ *of type* $\omega$.
*(2)* $\sum_{\mathcal{O}}\prod_{i=1}^k\mathcal{X}_i(\mathcal{O})=\mathbf{H}^{\boldsymbol{\mu}}_\omega(q)$ *where the sum is over the conjugacy classes of* $G^F$ *of type* $\omega$.

*Proof.* Let $\mathcal{X}$ be an irreducible character of type $\alpha\in\mathbf{T}_n$ and let $\mathcal{O}$ be a conjugacy class of $G^F$ of type $\beta\in\mathbf{T}_n$, we have (see Formula (2.6.2))

$$\mathcal{X}=\epsilon_G\epsilon_M|W_M|^{-1}\sum_{w\in W_M}\tilde{\varphi}(wF)R^G_{T_w}(\theta^{T_w}).$$

The $\mathbb{F}_q$-rank of $M$ is $f(\alpha)$, so $\epsilon_G\epsilon_M=(-1)^{n+f(\alpha)}$. Let $\sigma\in\mathcal{O}$, and put $L=C_G(\sigma_s)$. Then for $w\in W_M$,

$$R^G_{T_w}(\theta^{T_w})(\sigma)=|L^F|^{-1}\sum_{\{h\in G^F|\,\sigma\in h^{-1}T_wh\}}Q^L_{h^{-1}T_wh}(\sigma_u)\theta^{T_w}(h\sigma_sh^{-1}).$$

We have $\{h\in G^F|\,\sigma\in h^{-1}T_wh\}=\{h\in G^F|\,h^{-1}T_wh\subset L\}$. Put $A_w:=\{h\in G|\,h^{-1}T_wh\subset L\}$. Note that the sum over $A^F_w$ depends only on the $F$-conjugacy class of $w$ in $W_M$. The $F$-conjugacy classes of $W_M$, and so the $M^F$-conjugacy classes of the $F$-stable maximal tori of $M$, are parametrized by the set of types $\{\tau|\,\tau\sim\alpha\}$ as in §4.1. From its definition, the value $\tilde{\varphi}(wF)$ depends also only on the $F$-conjugacy class of $w$ in $W_M$. For $\tau\in\mathbf{T}_n$, we write $T_\tau$, $A_\tau$, $\tilde{\varphi}(\tau)$ instead of $T_w$, $A_w$, $\tilde{\varphi}(wF)$ if the $F$-conjugacy class of $w$ is of type $\tau$. Let $c(\tau)$ be the cardinality of the corresponding $F$-conjugacy class in $W_M$. Then

$$\mathcal{X}(\sigma)=(-1)^{n+f(\alpha)}|L^F|^{-1}\sum_{\tau\sim\alpha}\sum_{h\in A^F_\tau}\frac{c(\tau)}{|W_M|}\tilde{\varphi}(\tau)Q^L_{h^{-1}T_\tau h}(\sigma_u)\theta^{T_\tau}(h\sigma_sh^{-1}).$$

We have $c(\tau)/|W_M|=z_\tau^{-1}$ and $\tilde{\varphi}(\tau)=\chi^\alpha_\tau$. Hence

$$\mathcal{X}(\sigma)=(-1)^{n+f(\alpha)}|L^F|^{-1}\sum_\tau z_\tau^{-1}\chi^\alpha_\tau\sum_{h\in A^F_\tau}Q^L_{h^{-1}T_\tau h}(\sigma_u)\theta^{T_\tau}(h\sigma_sh^{-1}).$$

Since by convention $\chi^\alpha_\tau=0$ if $\tau\nsim\alpha$, we omit the condition $\tau\sim\alpha$ in the above sum. The map $h\mapsto h^{-1}T_\tau h$ is a surjective map from the set $A^F_\tau$ onto the set of $F$-stable maximal tori of $L$ that are in the $G^F$-conjugacy class (of $F$-stable maximal tori of $G$) of type $[\tau]\in\mathcal{P}_n$. Therefore it induces a surjective map $A^F_\tau/L^F\rightarrow\{\nu|\,\nu\sim\beta,[\nu]=[\tau]\}$. Hence

$$\mathcal{X}(\sigma)=(-1)^{n+f(\alpha)}\sum_{\tau}z_{\tau}^{-1}\chi_{\tau}^{\alpha}\sum_{\{\nu\,|\,[\nu]=[\tau]\}}Q_{\nu}^{\beta}(q)\sum_{l\in\overline{A}_{\nu}}\theta^{T_{\tau}}(l\sigma_s l^{-1}) \tag{4.3.2}$$

where $\overline{A}_{\nu}$ is the set of elements $lL^F$ of $A_{\tau}^F/L^F$ such that the $L^F$-conjugacy class of $l^{-1}T_{\tau}l$ is of type $\nu$.

Let us determine the set $\overline{A}_{\nu}$. The $L^F$-conjugacy classes of the $F$-stable maximal tori of $L^F$ are parametrized by the set $\{\nu|\,\nu\sim\beta\}$. Let $T_{\nu}$ denote an $F$-stable maximal torus of $L$ whose $L^F$-conjugacy class is of type $\nu\in\{\gamma|\,\gamma\sim\beta,[\gamma]=[\tau]\}$. Then the $G^F$-conjugacy class of $T_{\nu}$ is of type $[\nu]=[\tau]$ and so $T_{\nu}$ is $G^F$-conjugate to $T_{\tau}$, say $T_{\tau}=gT_{\nu}g^{-1}$ with $g\in G^F$. We put $B_{\nu}=\{h\in G|\,h^{-1}T_{\nu}h\subset L\}$. Then the map $h\mapsto g^{-1}h$ induces a bijection $(A_{\tau}^F/L^F)\simeq(B_{\nu}^F/L^F)$. Since the maximal tori of $L$ are all $L$-conjugate, the map $N_G(T_{\nu})\to(B_{\nu}/L)$, $n\mapsto nL$ is surjective and commutes with the Frobenius $F$. This map induces a bijection $(N_G(T_{\nu})/N_L(T_{\nu}))\xrightarrow{\sim}(B_{\nu}/L)$ which commutes with $F$. We thus have a bijection

$$(W_G(T_{\nu})/W_L(T_{\nu}))^F\xrightarrow{\sim}(B_{\nu}/L)^F.$$

Since $L$ is connected we get bijections

$$(W_G(T_{\nu})/W_L(T_{\nu}))^F\xrightarrow{\sim}(B_{\nu}^F/L^F)\simeq(A_{\tau}^F/L^F).$$

Under this bijection, the elements of $\overline{A}_{\nu}$ correspond to the elements $u\in(W_G(T_{\nu})/W_L(T_{\nu}))^F$ such that $(T_{\nu})_{\dot{u}^{-1}F(\dot{u})}$, $\dot{u}\in W_G(T_{\nu})$ being a representative of $u$, and $T_{\nu}$ are $L^F$-conjugate. Now saying that $(T_{\nu})_{\dot{u}^{-1}F(\dot{u})}$ and $T_{\nu}$ are $L^F$-conjugate is equivalent to saying that $\dot{u}^{-1}F(\dot{u})$ is in the $F$-conjugacy class of 1 in $W_L(T_{\nu})$, i.e., $\dot{u}^{-1}F(\dot{u})=w^{-1}F(w)$ for some $w\in W_L(T_{\nu})$. We know that $W_G(T_{\nu})/W_L(T_{\nu})\simeq\mathcal{S}_n/\prod_i(\mathcal{S}_{|\beta^i|})^{d_i}$. Under this bijection, the automorphism $F$ on $W_G(T_{\nu})$ induces an automorphism on $\mathcal{S}_n$ which stabilizes $\prod_i(\mathcal{S}_{|\beta^i|})^{d_i}$. Let us determine the automorphism obtained. Let $v_{\beta}$ be an element of $\mathcal{S}_n$ such that the automorphism $z\mapsto v_{\beta}zv_{\beta}^{-1}$ induces an action on each component of $\prod_i(\mathcal{S}_{|\beta^i|})^{d_i}$ by circular permutation of the $d_i$ blocks of length $|\beta^i|$. Then $(W_L,F)\simeq(\prod_i(\mathcal{S}_{|\beta^i|})^{d_i},v_{\beta})$. Now let $w_{\nu}\in\prod_i(\mathcal{S}_{|\beta^i|})^{d_i}$ be in the $v_{\beta}$-conjugacy class of $\prod_i(\mathcal{S}_{|\beta^i|})^{d_i}$ corresponding to $\nu$, then $(W_G(T_{\nu}),F)\simeq(\mathcal{S}_n,w_{\nu}v_{\beta})$, where $w_{\nu}v_{\beta}:\mathcal{S}_n\to\mathcal{S}_n, z\mapsto w_{\nu}v_{\beta}z(w_{\nu}v_{\beta})^{-1}$. We deduce that $\overline{A}_{\nu}$ is in bijection with the set $\overline{\mathcal{W}}_{\nu}$ of elements $x(\prod_i(\mathcal{S}_{|\beta^i|})^{d_i})$ with $x\in\mathcal{S}_n$ such that $x^{-1}(w_{\nu}v_{\beta})x=t(w_{\nu}v_{\beta})t^{-1}$ for some $t\in\prod_i(\mathcal{S}_{|\beta^i|})^{d_i}$.

Let us determine the cardinality of $\overline{A}_{\nu}$ as we will need it later. Put $H=\prod_i(\mathcal{S}_{|\beta^i|})^{d_i}$. We have a bijective map $C_{\mathcal{S}_n}(w_{\nu}v_{\beta})/C_H(w_{\nu}v_{\beta})\to\overline{\mathcal{W}}_{\nu}$, $xC_H(w_{\nu}v_{\beta})\mapsto xH$. But $|C_{\mathcal{S}_n}(w_{\nu}v_{\beta})|=z_{[\tau]}$ and $|C_H(w_{\nu}v_{\beta})|=z_{\nu}$, therefore

$$|\overline{A}_{\nu}|=|\overline{\mathcal{W}}_{\nu}|=z_{[\tau]}z_{\nu}^{-1}. \tag{4.3.3}$$

Now let us compute $\sum_{\mathcal{X}}\prod_i\mathcal{X}(C_i)$ and $\sum_{O}\prod_i\mathcal{X}_i(O)$. We first compute the second sum. Let $(L,C)$ be a pair of type $\omega$ where $L$ is an $F$-stable Levi subgroup and $C$ and $F$-stable unipotent conjugacy class of $L$. Let $u\in C$. We have a surjective map $(Z_L)_{\mathrm{reg}}^F\to\{G^F-\text{orbits of type }\omega\}$ that sends $z$ to $O_{zu}^{G^F}$. If $s,s'\in(Z_L)_{\mathrm{reg}}^F$, then $s$ and $s'$ have the same image if there exists $g\in G^F$ such that $g(sC)g^{-1}=s'C$,i.e., $gsg^{-1}=s'$ and $gCg^{-1}=C$. The identity $gsg^{-1}=s'$ implies that $g\in N_G(L)$. Therefore the fibers of our map can be identified with $W_G(L,C):=\{g\in G^F|\,g\in N_G(L)\cap N_G(C)\}/L^F$ which is of cardinality $|W(\omega)|$. We thus have

$$\sum_{O}\prod_{i=1}^{k}\mathcal{X}_i(O)=\frac{1}{|W(\omega)|}\sum_{z\in(Z_L)_{\mathrm{reg}}^F}\prod_{i=1}^{k}\mathcal{X}_i(zu).$$

Applying the Formula (4.3.2) with $(\alpha,\beta)=(\mu_i,\omega)$, we get

$$\sum_{O}\prod_{i=1}^{k}\mathcal{X}_i(O)=\frac{1}{|W(\omega)|}\sum_{\tau_1,\dots,\tau_k}\sum_{\{(\nu_1,\dots,\nu_k)|\,[\nu_i]=[\tau_i]\}}\prod_{i=1}^{k}\chi_{\tau_i}^{\mu_i}z_{\tau_i}^{-1}Q_{\nu_i}^{\omega}(q)$$

$$\sum_{(l_1,\dots,l_k)\in\overline{A}_{\nu_1}\times\dots\times\overline{A}_{\nu_k}}\left(\sum_{z\in(Z_L)_{\mathrm{reg}}^F}\prod_{i=1}^{k}\theta_i^{T_{\tau_i}}(l_izl_i^{-1})\right).$$

Put $\theta_i^{l_i^{-1}T_{\tau_i}l_i}(z) := \theta_i^{T_{\tau_i}}(l_izl_i^{-1})$ for all $z \in Z_L^F$. Then $\prod_i \theta_i^{l_i^{-1}T_{\tau_i}l_i}$ is a linear character of $Z_L^F$. By assumption, it is generic and so by Proposition 4.2.1, we have $\sum_{z\in(Z_L)^F_{\text{reg}}} \prod_i \theta^{l_i^{-1}T_{\tau_i}l_i}(z) = (q-1)K^o_\omega$, from which we deduce that:

$\sum_{\mathcal{O}} \prod_{i=1}^k \mathcal{X}_i(\mathcal{O}) =$

$$\frac{(q-1)K^o_\omega}{|W(\omega)|} \sum_{\tau_1,\dots,\tau_k} \sum_{\{(\nu_1,\dots,\nu_k)|\,[\nu_i]=[\tau_i]\}} \prod_{i=1}^k \chi^{\mu_i}_{\tau_i} z_{\tau_i}^{-1} Q^\omega_{\nu_i}(q)|\overline{\mathcal{W}}_{\nu_1}|\dots|\overline{\mathcal{W}}_{\nu_k}|.$$

The assertion (2) of the theorem follows then from the Formula (4.3.3).

Let us now compute $\sum_{\mathcal{X}} \prod_i \mathcal{X}(C_i)$. Let $(L,\chi)$ be of type $\omega$ with $L$ an $F$-stable Levi subgroup of $G$ and $\chi$ an $F$-stable irreducible character of $W_L$. Let $\mathcal{X}^L_\chi$ be the unipotent character of $L^F$ associated to $\chi$. The map $\text{Irr}_{\text{reg}}(L^F) \to \{\mathcal{X} \in \text{Irr}(G^F)|\,\mathcal{X} \text{ of type } \omega\}$ that sends $\theta$ to $\epsilon_G\epsilon_L R^G_L(\theta\cdot\mathcal{X}^L_\chi)$ is surjective and its fibers are of cardinality $|W(\omega)|$. We thus have

$$\sum_{\mathcal{X}} \prod_{i=1}^k \mathcal{X}(C_i) = \frac{1}{|W(\omega)|} \sum_{\theta\in\text{Irr}_{\text{reg}}(L^F)} \prod_{i=1}^k \epsilon_G\epsilon_L R^G_L(\theta\cdot\mathcal{X}^L_\chi)(C_i).$$

The value $\epsilon_G\epsilon_L R^G_L(\theta\cdot\mathcal{X}^L_\chi)(C_i)$ is of the form $\mathcal{X}(\sigma)$, see Formula (4.3.2), with $(\alpha,\beta) = (\omega,\mu_i)$. Hence

$$\sum_{\mathcal{X}} \prod_{i=1}^k \mathcal{X}(C_i) = \frac{1}{|W(\omega)|} \sum_{\tau_1,\dots,\tau_k} \sum_{\{(\nu_1,\dots,\nu_k)|\,[\nu_i]=[\tau_i]\}} \prod_{i=1}^k \chi^\omega_\tau z_{\tau_i}^{-1} Q^{\mu_i}_{\nu_i}(q)$$

$$\sum_{(l_1,\dots,l_k)\in\overline{A}_{\nu_1}\times\dots\times\overline{A}_{\nu_k}} \left( \sum_{\theta\in\text{Irr}_{\text{reg}}(L^F)} \prod_{i=1}^k \theta^{T_{\tau_i}}(l_i\sigma_{i,s}l_i^{-1}) \right)$$

where $\sigma_{i,s}$ is the semisimple part of some fixed element $\sigma_i \in C_i$. Recall that for $\theta \in \text{Irr}_{\text{reg}}(L^F)$, $\theta^{T_{\tau_i}}$ is the restriction of $\theta$ to $T^F_{\tau_i}$. The assertion (1) of the theorem follows from Proposition 4.2.3 and Formula (4.3.3). □

# 5 E-polynomial of character varieties

## 5.1 E-polynomial of character varieties

Fix a non-negative integer $g$ and choose $k$-generic semisimple conjugacy classes $C_1, C_2, \dots, C_k$ of $\text{GL}_n(\mathbb{C})$ of type $\boldsymbol{\mu} = (\mu^1,\dots,\mu^k)$ where $\mu^i = (\mu^i_1,\dots,\mu^i_{r_i})$ is a partition of $n$. Recall that the non-negative integers $\mu^i_1,\dots,\mu^i_{r_i}$ are the multiplicities of the distinct eigenvalues of $C_i$. A partition $\lambda = (n_1,\dots,n_r)$ of $n$ can be seen as the type $\lambda_* := (1,1^{n_1})\dots(1,1^{n_r}) \in \mathbf{T}_n$ which is the type of a semisimple conjugacy class in the sense of §4.1. Similarly when a multipartition $\boldsymbol{\lambda}$ is considered as a multitype it is denoted by $\boldsymbol{\lambda}_*$. Let $\mathcal{M}_{\boldsymbol{\mu}}$ be the corresponding complex character variety as defined in §2.1. In this section we prove that $\mathcal{M}_{\boldsymbol{\mu}}$ is polynomial-count and we give a close formula for $E(\mathcal{M}_{\boldsymbol{\mu}};q)$. This formula will be used to compute the Euler characteristic (see §5.2) and to prove the connectedness of $\mathcal{M}_{\boldsymbol{\mu}}$ [15].

The aim of this section is to prove the following theorem.

**Theorem 5.1.1.** *The variety $\mathcal{M}_{\boldsymbol{\mu}}$ is polynomial-count and its E-polynomial is given by*

$$E(\mathcal{M}_{\boldsymbol{\mu}};q) = q^{\frac{1}{2}d_{\boldsymbol{\mu}}}\mathbb{H}_{\boldsymbol{\mu}}\left(\sqrt{q}, \frac{1}{\sqrt{q}}\right)$$

*where $\mathbb{H}_{\boldsymbol{\mu}}(z,w)$ is as in the introduction and $d_{\boldsymbol{\mu}} = \dim(\mathcal{M}_{\boldsymbol{\mu}})$.*

The theorem has the following straightforward consequence:

**Corollary 5.1.2.** *The $E$-polynomial of $\mathcal{M}_\mu$ does not depend on the choice of the generic semisimple conjugacy classes $C_1, ..., C_k$ of a given type $\boldsymbol{\mu}$.*

Let $\mathcal{U}_\mu = \operatorname{Spec}(\mathcal{A})$ be the $R$-scheme defined in Appendix 7.1. Put $\mathcal{X}_\mu = \operatorname{Spec}(\mathcal{A}^{\mathrm{PGL}_n(R)})$. Then the $R$-scheme $\mathcal{X}_\mu$ is a *spreading out* of $\mathcal{M}_\mu$, i.e., $\mathcal{X}_\mu$ gives back $\mathcal{M}_\mu$ after extension of scalars from $R$ to $\mathbb{C}$. If $\phi : R \to k$ is a ring homomorphism into a field $k$, we denote by $\mathcal{M}_\mu^\phi$ the $k$-scheme obtained from $\mathcal{X}_\mu$ by extension of scalars.

**Theorem 5.1.3.** *For any finite field $\mathbb{F}_q$ and any ring homomorphism $\phi : R \to \mathbb{F}_q$,*

$$\#\{\mathcal{M}_\mu^\phi(\mathbb{F}_q)\} = q^{\frac{1}{2}d_\mu}\mathbb{H}_\mu\left(\sqrt{q}, \frac{1}{\sqrt{q}}\right).$$

It is clear that $\mathbb{H}_\mu^g(z,w) \in \mathbb{Q}(z,w)$. Hence Theorem 5.1.3 implies that there exists $Q(x) \in \mathbb{Q}(x)$ such that for all $r$ we have $\#\{\mathcal{M}_\mu^\phi(\mathbb{F}_{q^r})\} = Q(q^r)$. In particular $Q(x)$ is an integer for infinitely many integer values of $x$, hence $Q(x) \in \mathbb{Q}[x]$. Therefore $\mathcal{M}_\mu$ is polynomial-count and so Theorem 5.1.1 follows from Theorem 2.5.1 and Theorem 5.1.3.

To prove Theorem 5.1.3 we need some intermediate results.

Recall first (see §2.3) that given a family of symmetric functions $u_\lambda(\mathbf{x}; q, t) \in \Lambda(\mathbf{x})$ indexed by partitions, we extend its definition to type $\omega = (d_1, \omega^1)(d_2, \omega^2)...(d_r, \omega^r)$ by $u_\omega(\mathbf{x}; q, t) = \prod_j u_{\omega^j}(\mathbf{x}^{d_j}; q^{d_j}, t^{d_j})$.

**Lemma 5.1.4.** *For $\alpha, \beta \in \mathbf{T}$, put*

$$A(\alpha, \beta) := \sum_\tau \frac{z_{[\tau]}\chi_\tau^\alpha}{z_\tau} \sum_{\{\nu \mid [\nu]=[\tau]\}} \frac{Q_\nu^\beta(q)}{z_\nu}.$$

*Then $A(\alpha,\beta) = \langle s_\alpha(\mathbf{x}), \tilde{H}_\beta(\mathbf{x}; q)\rangle$ where for a partition $\lambda$, $s_\lambda(\mathbf{x}) \in \Lambda(\mathbf{x})$ is the Schur symmetric function and $\tilde{H}_\lambda(\mathbf{x}; q) = \sum_\nu \tilde{K}_{\nu\lambda}(q)s_\nu(\mathbf{x})$ the transformed Hall-Littlewood symmetric function.*

*Proof.* For $\omega \in \mathbf{T}$, define

$$a_\omega(\mathbf{x}) = \sum_\tau \chi_\tau^\omega \frac{p_\tau(\mathbf{x})}{z_\tau}, \text{ and } \quad b_\omega(\mathbf{x}) = \sum_\nu Q_\nu^\omega(q)\frac{p_\nu(\mathbf{x})}{z_\nu}$$

where $\{p_\lambda(\mathbf{x})\}_{\lambda\in\mathcal{P}}$ is the family of power symmetric functions which satisfies for two partitions $\lambda, \tau \in \mathcal{P}$,

$$\langle p_\lambda(\mathbf{x}), p_\tau(\mathbf{x})\rangle = \delta_{\lambda,\tau}z_\tau.$$

For a type $\omega \in \mathbf{T}$, we have $p_\omega(\mathbf{x}) := \prod_i p_{\omega^i}(\mathbf{x}^{d_i}) = p_{[\omega]}(\mathbf{x})$. Therefore for $\alpha, \beta \in \mathbf{T}$, we have $\langle p_\alpha(\mathbf{x}), p_\beta(\mathbf{x})\rangle = \delta_{[\alpha],[\beta]}z_{[\alpha]}$. Hence

$$\begin{aligned}\langle a_\alpha(\mathbf{x}), b_\beta(\mathbf{x})\rangle &= \sum_\tau \sum_\nu \chi_\tau^\alpha Q_\nu^\beta(q)\frac{\langle p_\tau(\mathbf{x}), p_\nu(\mathbf{x})\rangle}{z_\tau z_\nu}\\ &= \sum_\tau \sum_\nu \chi_\tau^\alpha Q_\nu^\beta(q)\frac{z_{[\tau]}}{z_\tau z_\nu}\\ &= A(\alpha,\beta).\end{aligned}$$

Recall that for a partition $\lambda \in \mathcal{P}$, we have

$$s_\lambda(\mathbf{x}) = \sum_\tau \chi^\lambda_\tau \frac{p_\tau(\mathbf{x})}{z_\tau}.$$

Hence for a type $\omega \in \mathbf{T}$, we have

$$s_\omega(\mathbf{x}) = \sum_\tau \chi^\omega_\tau \frac{p_\tau(\mathbf{x})}{z_\tau} = a_\omega(\mathbf{x}).$$

On the other hand the decomposition $Q^\tau_\lambda(q) = \sum_\nu \chi^\nu_\lambda \tilde{K}_{\nu\tau}(q)$ with $\lambda, \tau \in \mathcal{P}$ extends to types, i.e., for $\omega, \nu \in \mathbf{T}$, we have $Q^\omega_\nu(q) = \sum_\tau \chi^\tau_\nu \tilde{K}_{\tau\omega}(q)$. Hence we may write

$$\begin{aligned} b_\omega(\mathbf{x}) &= \sum_\nu \sum_\tau \chi^\tau_\nu \tilde{K}_{\tau\omega}(q) \frac{p_\nu(\mathbf{x})}{z_\nu} \\ &= \sum_\tau \sum_\nu \chi^\tau_\nu \tilde{K}_{\tau\omega}(q) \frac{p_\nu(\mathbf{x})}{z_\nu} \\ &= \sum_\tau \tilde{K}_{\tau\omega}(q) s_\tau(\mathbf{x}) = \tilde{H}_\omega(\mathbf{x}; q). \end{aligned}$$

The last equality is straightforward. □

Put

$$\Omega(z, w) := \sum_{\lambda \in \mathcal{P}} \mathcal{H}_\lambda(z, w) \prod_{i=1}^k \tilde{H}(\mathbf{x}_i; z^2, w^2),$$

where $\mathcal{H}_\lambda(z, w)$ is the genus $g$ hook function (see introduction and §2.4).

**Lemma 5.1.5.** *Let* $\mathbf{y} = \{y_1, y_2, ...\}$ *be a set of infinitely many variables. If* $\mathbf{x}$ *is another set of infinitely many variables, we denote by* $\mathbf{xy}$ *the set of variables* $\{x_i y_j\}_{i,j}$. *With the specialization* $y_i = q^{i-1}$, *we have*

$$\begin{aligned} \Omega\left(\sqrt{q}, \frac{1}{\sqrt{q}}\right) &= \sum_{\lambda \in \mathcal{P}} (q^{-n(\lambda)} H_\lambda(q))^k \mathcal{H}_\lambda\left(\sqrt{q}, \frac{1}{\sqrt{q}}\right) \prod_{i=1}^k s_\lambda(\mathbf{x}_i \mathbf{y}) \\ &= \sum_{\lambda \in \mathcal{P}} q^{(1-g)|\lambda|} (q^{-n(\lambda)} H_\lambda(q))^{2g+k-2} \prod_{i=1}^k s_\lambda(\mathbf{x}_i \mathbf{y}). \end{aligned}$$

*Proof.* Let $\tilde{K}_{\nu\lambda}(q, t)$ be defined as $\tilde{H}_\lambda(\mathbf{x}; q, t) = \sum_\nu \tilde{K}_{\nu\lambda}(q, t) s_\nu(\mathbf{x})$. For two partitions $\nu, \lambda \in \mathcal{P}_n$, we have [32, Page 363]

$$\tilde{K}_{\nu\lambda}(q, q^{-1}) = q^{-n(\lambda)} K_{\nu\lambda}(q, q) = q^{-n(\lambda)} H_\lambda(q) \sum_\rho \frac{\chi^\nu_\rho \chi^\lambda_\rho}{z_\rho \prod_i (1 - q^{\rho_i})}.$$

With the specialization $y_i = q^{i-1}$, we have $p_\rho(\mathbf{y}) = \prod_i (1 - q^{\rho_i})^{-1}$. Hence

$$\begin{aligned} \tilde{H}_\lambda(\mathbf{x}; q, q^{-1}) &= q^{-n(\lambda)} H_\lambda(q) \sum_{\rho, \nu} \frac{\chi^\nu_\rho \chi^\lambda_\rho}{z_\rho} p_\rho(\mathbf{y}) s_\nu(\mathbf{x}) \\ &= q^{-n(\lambda)} H_\lambda(q) \sum_\rho z_\rho^{-1} \chi^\lambda_\rho p_\rho(\mathbf{y}) \sum_\nu \chi^\nu_\rho s_\nu(\mathbf{x}) \\ &= q^{-n(\lambda)} H_\lambda(q) \sum_\rho z_\rho^{-1} \chi^\lambda_\rho p_\rho(\mathbf{y}) p_\rho(\mathbf{x}) \\ &= q^{-n(\lambda)} H_\lambda(q) \sum_\rho z_\rho^{-1} \chi^\lambda_\rho p_\rho(\mathbf{xy}) \\ &= q^{-n(\lambda)} H_\lambda(q) s_\lambda(\mathbf{xy}). \end{aligned}$$

We obtain therefore,

$$\begin{aligned}\Omega(\sqrt{q}, 1/\sqrt{q}) &= \sum_{\lambda\in\mathcal{P}} (q^{-n(\lambda)}H_\lambda(q))^k \mathcal{H}_\lambda(\sqrt{q}, 1/\sqrt{q}) \prod_{i=1}^{k} s_\lambda(\mathbf{x}_i y)\\ &= \sum_{\lambda\in\mathcal{P}} q^{(1-g)|\lambda|}(q^{-n(\lambda)}H_\lambda(q))^{k+2g-2} \prod_{i=1}^{k} s_\lambda(\mathbf{x}_i y).\end{aligned}$$

□

**Lemma 5.1.6.** *Let* $\mathbf{x}, \mathbf{y}$ *be as in Lemma 5.1.5 and let* $\lambda \in \mathcal{P}$*. With the specialization* $y_i = q^{i-1}$*, we have*

$$h_\lambda(\mathbf{xy}) = (-1)^{|\lambda|} q^{n(\lambda_*)} \mathcal{H}^0_{\lambda_*}(0, \sqrt{q}) \tilde{H}_{\lambda_*}(\mathbf{x}; q),$$

*where* $\mathcal{H}^0_\lambda(z, w)$ *is the genus* 0 *hook function.*

*Proof.* We need to prove that for $m \in \mathbb{Z}_{>0}$,

$$h_m(\mathbf{xy}) = (-1)^m q^{n(1^m)} \mathcal{H}^0_{(1^m)}(0, \sqrt{q}) \tilde{H}_{(1^m)}(\mathbf{x}; q).$$

In the language of plethystic substitution (we use the notation of [10]), the transformed Hall-Littlewood $\tilde{H}_\mu(\mathbf{x}; q)$ with $\mu \in \mathcal{P}$ is defined as

$$\tilde{H}_\mu(\mathbf{x}; q) = q^{n(\mu)} b_\mu(q^{-1}) P_\mu \left[\frac{X}{1-q^{-1}}; q^{-1}\right]$$

where $P_\mu(\mathbf{x}; q)$ is the Hall-Littlewood symmetric function defined in [32]. Since $\mathcal{H}^0_\mu(0, \sqrt{q}) = q^{-\langle\mu,\mu\rangle} b_\mu(q^{-1})^{-1}$, we have

$$(-1)^{|\mu|} q^{n(\mu)} \mathcal{H}^0_\mu(0, \sqrt{q}) \tilde{H}_\mu(\mathbf{x}; q) = (-1)^{|\mu|} q^{-|\mu|} P_\mu \left[\frac{X}{1-q^{-1}}; q^{-1}\right] \tag{5.1.1}$$

$$= (-q^{-1})^{|\mu|} P_\mu \left[-\frac{qX}{1-q}; q^{-1}\right] \tag{5.1.2}$$

On the other hand from [32, VI, (4.8)] we have $(-q^{-1})^m P_{(1^m)}\left[-qX; q^{-1}\right] = (-q^{-1})^m e_m\left[-qX\right] = (-q^{-1})^m s_{(1^m)}\left[-qX\right] = s_{(m^1)}(\mathbf{x}) = h_m(\mathbf{x})$. Since for any symmetric function $u$, we have $u(\mathbf{xy}) = u\left[\frac{X}{1-q}\right]$, we deduce that

$$h_m(\mathbf{xy}) = (-q^{-1})^m P_{(1^m)} \left[-\frac{qX}{1-q}; q^{-1}\right].$$

The lemma follows thus from Formula (5.1.2). □

We are now in position to prove Theorem 5.1.3.

*Proof.* Let $k$ be an algebraic closure of $\mathbb{F}_q$. Since $\mathrm{PGL}_n(k)$ is connected any $F$-stable $\mathrm{PGL}_n(k)$-orbit of $\boldsymbol{\mathcal{U}}^\phi_{\boldsymbol{\mu}}(k)$ contains an $F$-stable point, i.e., an $\mathbb{F}_q$-rational point. Hence the natural map

$$\boldsymbol{\mathcal{U}}^\phi_{\boldsymbol{\mu}}(\mathbb{F}_q)/\mathrm{PGL}_n(\mathbb{F}_q) \to \left(\boldsymbol{\mathcal{U}}^\phi_{\boldsymbol{\mu}}(k)/\mathrm{PGL}_n(k)\right)^F = \boldsymbol{\mathcal{M}}^\phi_{\boldsymbol{\mu}}(\mathbb{F}_q)$$

is surjective. The $k$-tuple of conjugacy classes $(C^\phi_1, ..., C^\phi_k)$ being generic, the group $\mathrm{PGL}_n(\mathbb{F}_q)$ acts freely on $\boldsymbol{\mathcal{U}}^\phi_{\boldsymbol{\mu}}(\mathbb{F}_q)$, and so the above map is injective. Hence

$$\#\{\boldsymbol{\mathcal{M}}^\phi_{\boldsymbol{\mu}}(\mathbb{F}_q)\} = \frac{\#\{\boldsymbol{\mathcal{U}}^\phi_{\boldsymbol{\mu}}(\mathbb{F}_q)\}}{|\mathrm{PGL}_n(\mathbb{F}_q)|}.$$

Let $\mathrm{Irr}(G^F)_\omega$ denote the set of irreducible characters of type $\omega$. We denote by $\mathcal{X}_\omega(1)$ the degree of the irreducible characters in $\mathrm{Irr}(G^F)_\omega$. For $i \in \{1, ..., k\}$, let $C_i$ be the conjugacy class $C_i^\phi(\mathbb{F}_q)$ of $G^F = \mathrm{GL}_n(\mathbb{F}_q)$. From Proposition 3.1.4 and Theorem 4.3.1(1), we have

$$\begin{aligned}
\#\{\mathcal{U}_{\boldsymbol{\mu}}^\phi(\mathbb{F}_q)\} &= |G^F|^{2g-1} \sum_{\mathcal{X}\in\mathrm{Irr}(G^F)} \frac{1}{\mathcal{X}(1)^{2g-2+k}} \prod_{i=1}^k |C_i|\mathcal{X}(C_i) \\
&= \sum_{\omega\in\mathbf{T}_n} \frac{|G^F|^{2g-1}\prod_{i=1}^k |C_i|}{\mathcal{X}_\omega(1)^{2g-2+k}} \sum_{\mathcal{X}\in\mathrm{Irr}(G^F)_\omega} \prod_{i=1}^k \mathcal{X}(C_i) \\
&= \sum_{\omega\in\mathbf{T}_n} \frac{|G^F|^{2g-1}\prod_{i=1}^k |C_i|}{\mathcal{X}_\omega(1)^{2g-2+k}} \hat{\mathbf{H}}_\omega^{\boldsymbol{\mu}_*}(q) \\
&= \sum_{\omega\in\mathbf{T}_n} \frac{|G^F|^{2g-1}(q-1)K_\omega^o\prod_{i=1}^k |C_i|}{|W(\omega)|\mathcal{X}_\omega(1)^{2g-2+k}} (-1)^{kn+kf(\omega)} \prod_{i=1}^k A(\omega,\mu^i)
\end{aligned}$$

with $A(\omega, \mu_*^i)$ as in Lemma 5.1.4 where $\mu_*^i$ is the type in $\mathbf{T}_n$ corresponding to the partition $\mu^i$, see beginning of this section. For a type $\omega = (d_1, \omega^1)...(d_r, \omega^r)$, recall (see [32, IV, 6.7])

$$\frac{|G^F|}{\mathcal{X}_\omega(1)} = (-1)^{f(\omega)} H_\omega(q) q^{\frac{1}{2}n(n-1)-n(\omega)}$$

where $n(\omega) = \sum_j d_j n(\omega^j)$. Recall also (see §2.4) that $\mathcal{H}_{\mu_*^i}^0(0, \sqrt{q}) = |G^F|/|C_i|$ and note that $C_\omega^o = K_\omega^o/|W(\omega)|$, see Formula (2.3.9) and Proposition 4.2.1. Using also Lemma 5.1.4, we thus deduce that:

$$\begin{aligned}
&\#\{\mathcal{U}_{\boldsymbol{\mu}}^\phi(\mathbb{F}_q)\} \\
&= |G^F|(q-1) \sum_{\omega\in\mathbf{T}_n} \left((-1)^{f(\omega)} H_\omega(q) q^{\frac{1}{2}n(n-1)-n(\omega)}\right)^{2g+k-2} C_\omega^o (-1)^{kn+kf(\omega)} \prod_{i=1}^k \left\langle s_\omega(\mathbf{x}_i), \mathcal{H}_{\mu_*^i}^0(0, \sqrt{q}) \tilde{H}_{\mu_*^i}(\mathbf{x}_i; q)\right\rangle \\
&= |G^F|(q-1)(-1)^{kn} q^{\frac{1}{2}n(n-1)(2g+k-2)} \sum_{\omega\in\mathbf{T}_n} C_\omega^o \left(H_\omega(q) q^{-n(\omega)}\right)^{2g+k-2} \prod_{i=1}^k \left\langle s_\omega(\mathbf{x}_i), \mathcal{H}_{\mu_*^i}^0(0, \sqrt{q}) \tilde{H}_{\mu_*^i}(\mathbf{x}_i; q)\right\rangle \\
&= |G^F|(q-1)(-1)^{kn} q^{\frac{1}{2}(n^2(k+2g-2)-kn)} \\
&\qquad \left\langle \sum_{\omega\in\mathbf{T}} C_\omega^o q^{(1-g)|\omega|} \left(H_\omega(q) q^{-n(\omega)}\right)^{2g+k-2} \prod_{i=1}^k s_\omega(\mathbf{x}_i), \prod_{i=1}^k \mathcal{H}_{\mu_*^i}^0(0, \sqrt{q}) \tilde{H}_{\mu_*^i}(\mathbf{x}_i; q)\right\rangle \\
&= |G^F|(q-1)(-1)^{kn} q^{\frac{1}{2}(n^2(k+2g-2)-kn)} \\
&\qquad \left\langle \mathrm{Log}\left(\sum_{\lambda\in\mathcal{P}} q^{(1-g)|\lambda|} \left(H_\lambda(q) q^{-n(\lambda)}\right)^{2g+k-2} \prod_{i=1}^k s_\lambda(\mathbf{x}_i)\right), \prod_{i=1}^k \mathcal{H}_{\mu_*^i}^0(0, \sqrt{q}) \tilde{H}_{\mu_*^i}(\mathbf{x}_i; q)\right\rangle \\
&= |G^F|(q-1) q^{\frac{1}{2}(n^2(k+2g-2)-kn)-\sum_i n(\mu_*^i)} \left\langle \mathrm{Log}\left(\sum_{\lambda\in\mathcal{P}} q^{(1-g)|\lambda|} \left(H_\lambda(q) q^{-n(\lambda)}\right)^{2g+k-2} \prod_{i=1}^k s_\lambda(\mathbf{x}_i)\right), \prod_{i=1}^k h_{\mu^i}(\mathbf{x}_i\mathbf{y})\right\rangle.
\end{aligned}$$

In the third equality $|\omega|$ is defined as the size of $\omega$, i.e., $|\omega| = n$ if $\omega \in \mathbf{T}_n$. The last equality follows from Lemma 5.1.6. For any symmetric functions $u$ and $v$, $\langle u(\mathbf{xy}), v(\mathbf{x})\rangle = \langle u(\mathbf{x}), v(\mathbf{xy})\rangle$. This can be checked on the basis of power symmetric functions. We deduce from Lemma 5.1.5 that

$$\#\{\mathcal{U}_{\boldsymbol{\mu}}^\phi(\mathbb{F}_q)\} = |G^F|(q-1) q^{\frac{1}{2}(n^2(k+2g-2)-kn)-\sum_i n(\mu_*^i)} \left\langle \mathrm{Log}\left(\Omega(\sqrt{q}, 1/\sqrt{q})\right), \prod_{i=1}^k h_{\mu^i}(\mathbf{x}_i)\right\rangle.$$

We thus have

$$\#\{\mathcal{M}_{\mu}^{\phi}(\mathbb{F}_q)\} = (q-1)^2 q^{\frac{1}{2}(n^2(k+2g-2)-kn)-\sum_i n(\mu^i_*)} \left\langle \mathrm{Log}\,(\Omega(\sqrt{q}, 1/\sqrt{q}))\,, \prod_{i=1}^{k} h_{\mu^i}(\mathbf{x}_i) \right\rangle.$$

We have $\mathbb{H}_{\mu}(\sqrt{q}, 1/\sqrt{q}) = \frac{(q-1)^2}{q} \left\langle \mathrm{Log}\left(\Omega(\sqrt{q}, 1/\sqrt{q})\right), \prod_{i=1}^{k} h_{\mu^i}(\mathbf{x}_i)\right\rangle$. It remains to check that the remaining power of $q$ is $d_{\mu}/2$, but this follows from the observation that $\langle \mu^i_*, \mu^i_* \rangle = 2n(\mu^i_*) + n = \sum_j (\mu^i_j)^2$. □

Here we can prove a consequence of the Curious Poincaré duality Conjecture 1.1.2:

**Corollary 5.1.7.** *The E-polynomial is palindromic i.e. satisfies the "curious" Poincaré duality:*

$$\begin{aligned} E(\mathcal{M}_{\mu}; q) &= q^{d_{\mu}} E(\mathcal{M}_{\mu}; q^{-1}) \\ &= \sum_i \left( \sum_k (-1)^k h^{i,i;k}(\mathcal{M}_{\mu}) \right) q^i \end{aligned}$$

*Proof.* By Theorem 2.1.5 the variety $\mathcal{M}_{\mu}$ is non-singular of pure dimension $d_{\mu}$. Hence the second equality is a consequence of Formula (2.5.1). From Theorem 5.1.1 we have

$$\begin{aligned} E(\mathcal{M}_{\mu}; q^{-1}) &= q^{-d_{\mu}/2} \mathbb{H}_{\mu}(1/\sqrt{q}, \sqrt{q}) \\ &= q^{-d^g_{\mu}/2} \frac{(q-1)^2}{q} \left\langle \prod_i h_{\mu^i}(\mathbf{x}_i), \mathrm{Log}\,(\Omega(1/\sqrt{q}, \sqrt{q})) \right\rangle \end{aligned}$$

We have $\mathrm{Log}\,(\Omega(1/\sqrt{q}, \sqrt{q})) = \sum_{\lambda} \left( \prod_i \tilde{H}_{\lambda}(\mathbf{x}_i; q^{-1}, q) \right) \mathcal{H}_{\lambda}(1/\sqrt{q}, \sqrt{q})$. Recall that

$$\mathcal{H}^g_{\lambda}(1/\sqrt{q}, \sqrt{q}) = (q^{\frac{1}{2}\langle \lambda, \lambda \rangle} H_{\lambda}(q^{-1}))^{2g-2}$$

and that $H_{\lambda}(q^{-1}) = (-1)^{|\lambda|} q^{-n(\lambda)-n(\lambda')-|\lambda|} H_{\lambda}(q)$. Since $\langle \lambda, \lambda \rangle = 2n(\lambda) + |\lambda|$, we deduce that

$$\mathcal{H}^g_{\lambda}(1/\sqrt{q}, \sqrt{q}) = \mathcal{H}^g_{\lambda'}(\sqrt{q}, 1/\sqrt{q}).$$

Let us compute $\tilde{H}_{\lambda}(\mathbf{x}; q^{-1}, q)$. Using the calculations in Proposition 5.1.5 and noticing that $p_{\rho}(\mathbf{y}^{-1}) = q^{|\rho|}(-1)^{\ell(\rho)} p_{\rho}(\mathbf{y})$, we see that $\tilde{H}_{\lambda}(\mathbf{x}; q^{-1}, q) = \tilde{H}_{\lambda'}(\mathbf{x}; q, q^{-1})$. We thus conclude that $\Omega(1/\sqrt{q}, \sqrt{q}) = \Omega(\sqrt{q}, 1/\sqrt{q})$, from which we get that

$$E(\mathcal{M}_{\mu}; q^{-1}) = q^{-d_{\mu}/2} \frac{(q-1)^2}{q} \left\langle \prod_i h_{\mu^i}(\mathbf{x}_i), \mathrm{Log}\,(\Omega(\sqrt{q}, 1/\sqrt{q})) \right\rangle = q^{-d^g_{\mu}} E(\mathcal{M}_{\mu}; q)$$

□

## 5.2 Euler characteristic of character varieties

The $2g$-dimensional torus $(\mathbb{C}^{\times})^{2g}$ acts freely on the character variety $\mathcal{M}_{\mu}$ by scalar multiplication on the first $2g$ coordinates. Let $\tilde{\mathcal{M}}_{\mu}$ be the GIT quotient $(\mathcal{M}_{\mu})//(\mathbb{C}^{\times})^{2g}$. For a ring homomorphism $\phi : R \to \mathbb{F}_q$ let $\mathcal{M}^{\phi}_{\mu}$ and $\tilde{\mathcal{M}}^{\phi}_{\mu}$ be the corresponding base changes to $\mathbb{F}_q$. We have

$$\#\{\tilde{\mathcal{M}}^{\phi}_{\mu}(\mathbb{F}_q)\} = \frac{\#\{\mathcal{M}^{\phi}_{\mu}(\mathbb{F}_q)\}}{(q-1)^{2g}}$$

i.e., $E(\mathcal{M}_{\mu}; q) = E\left((\mathbb{C}^{\times})^{2g}; q\right) \times E(\tilde{\mathcal{M}}_{\mu}; q)$. In particular $E(\mathcal{M}_{\mu}) = 0$ if $g > 0$. Here we compute $E(\tilde{\mathcal{M}}_{\mu})$. We need the following lemma.

**Lemma 5.2.1.** *Let $\lambda \in \mathcal{P}_n$ and let $d$ be a positive integer such that $d \mid n$. Then*

$$\langle p_{(d^{n/d})}, h_\lambda \rangle = \begin{cases} \frac{(n/d)!}{\prod_i \rho_i!} & \textit{if } \lambda = d \cdot \rho \textit{ for some } \rho = (\rho_1, \rho_2, \ldots) \in \mathcal{P}_{n/d} \\ 0 & \textit{otherwise.} \end{cases}$$

*Proof.* For a finite group $G$ let $\langle \cdot, \cdot \rangle_G$ denote the standard inner product on class functions of $G$. Using the Frobenius characteristic map [32, I,7] we have, for any two partitions $\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_r)$ and $\mu = (\mu_1, \mu_2, \ldots, \mu_s)$ of size $n$,

$$\langle p_\mu, h_\lambda \rangle = z_\mu \langle \delta_\mu, \mathrm{Ind}_{\mathcal{S}_\lambda}^{\mathcal{S}_n}(1) \rangle_{\mathcal{S}_n},$$

where $\delta_\mu(\sigma) = 1$ if $\sigma \in \mathcal{S}_n$ has cycle type $\mu$ and $\delta_\mu(\sigma) = 0$ otherwise, $\mathcal{S}_\lambda := \mathcal{S}_{\lambda_1} \times \mathcal{S}_{\lambda_2} \times \cdots \times \mathcal{S}_{\lambda_r} \subseteq \mathcal{S}_n$ and $z_\mu$ is the index of the centralizer in $\mathcal{S}_n$ of any element of cycle type $\mu$.

Hence, by Frobenius reciprocity

$$\langle p_\mu, h_\lambda \rangle = z_\mu \langle \mathrm{Res}_{\mathcal{S}_\lambda}^{\mathcal{S}_n} \delta_\mu, 1 \rangle_{\mathcal{S}_\lambda}.$$

The only non-zero terms contributing to the sum implicit in the right hand side are those elements of $\mathcal{S}_\lambda$ with cycle type $(\mu^1, \ldots, \mu^r)$ with $|\mu^i| = \lambda_i$ and $\cup_i \mu^i = \mu$. If $\mu = (d^{n/d})$ this forces $d \mid \lambda_i$ and $\mu^i = (d^{\rho_i})$, where $\rho_i := \lambda_i / d$ and the claim follows. □

**Theorem 5.2.2.** *Assume that $g > 1$, then*

$$E(\tilde{\mathcal{M}}_{\boldsymbol{\mu}}) = \begin{cases} \mu(n)\, n^{2g-3} & \textit{if } \boldsymbol{\mu} = ((n^1), \ldots, (n^1)) \\ 0 & \textit{otherwise} \end{cases}$$

*where $\mu$ is the ordinary Möbius function.*

*Proof.* First note that

$$E(\tilde{\mathcal{M}}_{\boldsymbol{\mu}}) = \left. \frac{\langle h_{\boldsymbol{\mu}}, \mathrm{Log}(\Omega(\sqrt{q}, 1/\sqrt{q})) \rangle}{(q-1)^{2g-2}} \right|_{q=1}, \tag{5.2.1}$$

where, as before, $h_{\boldsymbol{\mu}} := \prod_{i=1}^k h_{\mu^i}(\mathbf{x}_i)$. We have by §2.4

$$\Omega(\sqrt{q}, 1/\sqrt{q}) = \sum_{\lambda \in \mathcal{P}} A_\lambda,$$

where

$$A_\lambda := \left( q^{-\frac{1}{2}\langle \lambda, \lambda \rangle} H_\lambda(q) \right)^{2g-2} \prod_{i=1}^k \tilde{H}_\lambda(\mathbf{x}_i; q, q^{-1}). \tag{5.2.2}$$

Let $U_n = U_n(\mathbf{x}_1, \ldots, \mathbf{x}_k; q)$ be defined by

$$\log\left(\Omega(\sqrt{q}, 1/\sqrt{q})\right) = \sum_{n \geq 1} \frac{1}{n} U_n(\mathbf{x}_1, \ldots \mathbf{x}_k; q)$$

then as in (2.3.5)

$$\frac{U_n}{n} = \sum_{m_\lambda} (-1)^{m-1} (m-1)! \prod_\lambda \frac{A_\lambda^{m_\lambda}}{m_\lambda!} \tag{5.2.3}$$

where $m := \sum_\lambda m_\lambda$ and the sum is over all sequences $\{m_\lambda\}$ of non-negative integers such that $\sum_\lambda m_\lambda |\lambda| = n$. Since $(q-1)^{|\lambda|}$ divides $H_\lambda(q)$ also $(q-1)^{(2g-2)n}$ divides $U_n$ as it divides each term in the sum (5.2.3). Let $V_n = V_n(\mathbf{x}_1, \ldots \mathbf{x}_k; q)$ be defined by

$$\mathrm{Log}(\Omega(\sqrt{q}, 1/\sqrt{q})) = \sum_{n \geq 1} V_n(\mathbf{x}_1, \ldots, \mathbf{x}_k; q),$$

then by (2.3.4)

$$\left\langle h_{\boldsymbol{\mu}}, \mathrm{Log}(\Omega(\sqrt{q}, 1/\sqrt{q}))\right\rangle = \langle h_{\boldsymbol{\mu}}, V_n\rangle = \frac{1}{n}\sum_{d|n}\mu(d)\left\langle h_{\boldsymbol{\mu}}, U_{n/d}(\mathbf{x}_1^d, \ldots, \mathbf{x}_k^d; q^d)\right\rangle.$$

Since $(q-1)^{(2g-2)(n/d)}$ divides $U_{n/d}(\mathbf{x}_1^d, \ldots, \mathbf{x}_k^d; q^d)$ for all $d$, we have

$$\left.\frac{\langle h_{\boldsymbol{\mu}}, V_n\rangle}{(q-1)^{2g-2}}\right|_{q=1} = \tfrac{1}{n}\mu(n)\left\langle h_{\boldsymbol{\mu}}, \left.\frac{U_1(\mathbf{x}_1^n, \ldots, \mathbf{x}_k^n; q^n)}{(q-1)^{2g-2}}\right|_{q=1}\right\rangle$$

But

$$U_1(\mathbf{x}_1^n, \ldots, \mathbf{x}_k^n; q^n) = q^{n(g-1)}(q^n-1)^{2g-2}\prod_{i=1}^{k}\tilde{H}_{(1)}(\mathbf{x}_i^n; q^n, q^{-n})$$

and $\tilde{H}_{(1)}(\mathbf{x}^n) = p_{(1)}(\mathbf{x}^n) = p_{(n^1)}(\mathbf{x})$. Hence

$$\begin{aligned}\left.\frac{\langle h_{\boldsymbol{\mu}}, V_n\rangle}{(q-1)^{2g-2}}\right|_{q=1} &= \frac{1}{n}\mu(n)n^{2g-3}\prod_{i=1}^{k}\langle h_{\mu^i}(\mathbf{x}_i), p_{(n^1)}(\mathbf{x}_i)\rangle \\ &= \begin{cases}\tfrac{1}{n}\mu(n)n^{2g-3} & \text{if } \boldsymbol{\mu} = ((n^1), \ldots, (n^1)) \\ 0 & \text{otherwise}\end{cases}.\end{aligned}$$

The last equality follows from Lemma 5.2.1 □

**Theorem 5.2.3.** *For $g = 1$*

$$E(\tilde{\mathcal{M}}_{\boldsymbol{\mu}}) = \frac{1}{n}\sum_{d|\gcd(\mu_i^j)}\sigma(n/d)\mu(d)\frac{(n/d)^k}{\prod_{i,j}\mu_i^j!}.$$

*where $\sigma(m) = \sum_{d|m} d$.*

*Proof.* By [32, VI, (8.16)], we have $K_{\lambda\mu}(1,1) = \chi^{\lambda}_{(1^n)} = n!/h(\lambda)$ where $h(\lambda)$ is the hook length of $\lambda$ and so for a partition $\mu$ of size $n$, we have [32, I, p.66]

$$\tilde{H}_\mu(\mathbf{x}; 1, 1) = \sum_{\lambda}\frac{n!}{h(\lambda)}s_\lambda(\mathbf{x}) = e_1(\mathbf{x})^n = h_1(\mathbf{x})^n.$$

Hence

$$\Omega(1,1) = \sum_{\lambda} h_{\boldsymbol{\mu}}^{|\lambda|} = \prod_{m\geq 1}\left(1 - h_{\boldsymbol{\mu}}^m\right)^{-1} \tag{5.2.4}$$

by Euler's formula. As before, let $U_n = U_n(\mathbf{x}_1, \ldots, \mathbf{x}_k)$ and $V_n = V_n(\mathbf{x}_1, \ldots, \mathbf{x}_k)$ be the coefficients of $\log\left(\Omega_k^1(1,1)\right)$ and $\mathrm{Log}\left(\Omega_k^1(1,1)\right)$ respectively. Then $U_n = \sigma(n)h_{\boldsymbol{\mu}}$ and

$$\begin{aligned}\left\langle h_{\boldsymbol{\mu}}, \mathrm{Log}\,(\Omega(1,1))\right\rangle &= \left\langle h_{\boldsymbol{\mu}}, V_n\right\rangle \\ &= \frac{1}{n}\sum_{d|n}\sigma(n/d)\mu(d)\prod_{i=1}^{k}\langle h_1(\mathbf{x}_i^d)^{n/d}, h_{\mu_i}(\mathbf{x}_i)\rangle \\ &= \frac{1}{n}\sum_{d|n}\sigma(n/d)\mu(d)\prod_{i=1}^{k}\langle p_{(d^{n/d})}(\mathbf{x}_i), h_{\mu^i}(\mathbf{x}_i)\rangle \\ &= \frac{1}{n}\sum_{d|\gcd(\mu_j^i)}\sigma(n/d)\mu(d)\frac{(n/d)^k}{\prod_{i,j}\mu_i^j!}.\end{aligned}$$

The last equality follows from Lemma 5.2.1. □

*Remark* 5.2.4. The task to evaluate the Euler characteristic when $g = 0$ is more complicated, due to the presence of high order poles in $\mathcal{H}_\lambda^0(\sqrt{q}, 1/\sqrt{q})$ of §2.4 at $q = 1$.

# 6 The pure part of $\mathbb{H}_\mu(z,w)$

In this section we fix once and for all a multipartition $\boldsymbol{\mu} = (\mu^1, ..., \mu^k) \in (\mathcal{P}_n)^k$ where $\mu^i = (\mu^i_1, ..., \mu^i_{r_i})$. We are interested in the specialization $(z,w) \mapsto (0,w)$ of $\mathbb{H}_{\boldsymbol{\mu}}(z,w)$ which we call the *pure part* of $\mathbb{H}_{\boldsymbol{\mu}}(z,w)$, see the introduction. Here we give both a representation theoretical and a cohomological interpretation of $\mathbb{H}^g_{\boldsymbol{\mu}}(0,w)$.

## 6.1 Multiplicities in tensor products

In this section $G = \mathrm{GL}_n(\overline{\mathbb{F}}_q)$. For a partition $\mu = (n_1, ..., n_r)$ we define $\mu_\dagger$ to be the type $(1,(n_1)^1)...(1,(n_r)^1) \in \mathbf{T}$. Let $(\mathcal{X}_1, ..., \mathcal{X}_k)$ be a generic tuple of $k$-irreducible characters of type $\boldsymbol{\mu}_\dagger := (\mu^1_\dagger, ..., \mu^k_\dagger) \in \mathbf{T}_n$. The irreducible characters $\mathcal{X}_1, ..., \mathcal{X}_k$ are then semisimple. Put

$$R_{\boldsymbol{\mu}} := \bigotimes_{i=1}^k \mathcal{X}_i.$$

Let $\Lambda : G^F \to \overline{\mathbb{Q}}_\ell$ be defined by $x \mapsto q^{g \dim C_G(x)}$. Note that the map $g \mapsto q^{\dim C_G(x)}$ is the character of the representation of $G^F$ in the group algebra $\overline{\mathbb{Q}}_\ell[\mathfrak{g}^F]$ where $G^F$ acts on $\mathfrak{g}^F$ by the adjoint action.

Let $\langle \cdot, \cdot \rangle_{G^F}$ be the non-degenerate bilinear form on $C(G^F)$ defined by

$$\langle f, g \rangle_{G^F} = |G^F|^{-1} \sum_{x \in G^F} f(x)\overline{g(x)}.$$

**Theorem 6.1.1.** *We have*

$$\left\langle \Lambda \otimes R_{\boldsymbol{\mu}}, 1 \right\rangle_{G^F} = \mathbb{H}_{\boldsymbol{\mu}}(0, \sqrt{q}).$$

*Proof.* Notice that if $C$ is a conjugacy class of $G^F$ of type $\omega \in \mathbf{T}_n$, then $\mathcal{H}_\omega(0, \sqrt{q}) = q^{g\dim C_G(x)}|C|/|G^F|$ where $x \in C$. Hence by Theorem 4.3.1(2)

$$\begin{aligned}
\left\langle \Lambda \otimes \bigotimes_{i=1}^k \mathcal{X}_i, \mathrm{Id} \right\rangle_{G^F} &= \sum_C \frac{|C|}{|G^F|} \Lambda(C) \prod_{i=1}^k \mathcal{X}_i(C) \\
&= \sum_{\omega \in \mathbf{T}_n} \mathcal{H}_\omega(0, \sqrt{q}) \mathbf{H}^{\boldsymbol{\mu}_\dagger}_\omega(q) \\
&= \sum_{\omega \in \mathbf{T}_n} \frac{(q-1)K^o_\omega}{|W(\omega)|} \mathcal{H}_\omega(0, \sqrt{q}) \prod_{i=1}^k (-1)^{n+f(\mu^i_\dagger)} \left\langle s_{\mu^i_\dagger}(\mathbf{x}_i), \tilde{H}_\omega(\mathbf{x}_i; q) \right\rangle \\
&= (-1)^{kn + \sum_i f(\mu^i_\dagger)} \sum_{\omega \in \mathbf{T}_n} (q-1) C^o_\omega \mathcal{H}_\omega(0, \sqrt{q}) \left\langle \prod_i s_{\mu^i_\dagger}(\mathbf{x}_i), \prod_i \tilde{H}_\omega(\mathbf{x}_i; q) \right\rangle \\
&= (-1)^{kn + \sum_i f(\mu^i_\dagger)} (q-1) \left\langle \prod_i s_{\mu^i_\dagger}(\mathbf{x}_i), \sum_{\omega \in \mathbf{T}_n} C^o_\omega \mathcal{H}_\omega(0, \sqrt{q}) \prod_i \tilde{H}_\omega(\mathbf{x}_i; q) \right\rangle \\
&= (q-1) \left\langle \prod_i h_{\mu^i}(\mathbf{x}_i), \mathrm{Log}\left(\Omega(0, \sqrt{q})\right) \right\rangle
\end{aligned}$$

The last equality follows from the fact that $f(\mu^i_\dagger) = n$ and $s_{\mu^i_\dagger}(\mathbf{x}) = s_{(\mu^i_1)^1}(\mathbf{x})...s_{(\mu^i_{r_i})^1}(\mathbf{x}) = h_{\mu^i}(\mathbf{x})$. □

## 6.2 Poincaré polynomial of quiver varieties

Here we assume that $\boldsymbol{\mu}$ is indivisible so that we can choose a generic tuple $(\mathcal{O}_1, ..., \mathcal{O}_k)$ of semisimple adjoint orbits of $\mathfrak{gl}_n(\mathbb{C})$ of type $\boldsymbol{\mu}$. Let $\mathcal{Q}_{\boldsymbol{\mu}}$ be the corresponding complex quiver variety as in §2.2.

The aim of this section is to prove the following theorem.

**Theorem 6.2.1.** *The compactly supported Poincaré polynomial of $\mathcal{Q}_{\boldsymbol{\mu}}$ is given by*

$$P_c(\mathcal{Q}_{\boldsymbol{\mu}}; t) = t^{d_{\boldsymbol{\mu}}}\mathbb{H}_{\boldsymbol{\mu}}(0, t).$$

As we did for the character variety in Appendix 7.1, we define a spreading out $\mathcal{Y}_{\boldsymbol{\mu}}/\mathcal{R}$ of $\mathcal{Q}_{\boldsymbol{\mu}}$ such that for any ring homomorphism $\phi : \mathcal{R} \to \mathbb{K}$ into an algebraically closed field $\mathbb{K}$, the adjoint orbits $\mathcal{O}_1^\phi, ..., \mathcal{O}_k^\phi$ of $\mathfrak{gl}_n(\mathbb{K})$ are generic and of same type as $\mathcal{O}_1, ..., \mathcal{O}_k$. Let $\mathcal{Q}_{\boldsymbol{\mu}}^\phi$ denote the corresponding quiver variety over $\mathbb{K}$.

**Theorem 6.2.2.** *For any finite field $\mathbb{F}_q$ and any ring homomorphism $\phi : \mathcal{R} \to \mathbb{F}_q$ we have*

$$\#\{\mathcal{Q}_{\boldsymbol{\mu}}^\phi(\mathbb{F}_q)\} = q^{\frac{1}{2}d_{\boldsymbol{\mu}}}\mathbb{H}_{\boldsymbol{\mu}}(0, \sqrt{q}). \tag{6.2.1}$$

Theorem 6.2.1 follows from Proposition 2.5.2 and Theorem 6.2.2. Indeed, Theorem 6.2.2 implies that $\mathcal{Q}_{\boldsymbol{\mu}}^g/\mathbb{C}$ is polynomial-count (see remark just after Theorem 5.1.3).

We now prove Theorem 6.2.2.

For $i \in \{1, ..., k\}$, let $O_i$ be the adjoint orbit $\mathcal{O}_i^\phi(\mathbb{F}_q)$ of $\mathfrak{g}^F = \mathfrak{gl}_n(\mathbb{F}_q)$. As in the character variety case we show that

$$\#\{\mathcal{Q}_{\boldsymbol{\mu}}^\phi(\mathbb{F}_q)\} = \frac{\#\{\mathcal{V}_{\boldsymbol{\mu}}^\phi(\mathbb{F}_q)\}}{|\mathrm{PGL}_n(\mathbb{F}_q)|}.$$

Let $\Lambda : \mathfrak{g}^F \to \overline{\mathbb{Q}}_\ell$, $x \mapsto q^{g \dim C_G(x)}$. By Proposition 3.2.2 and Remark 3.2.3, we have

$$\begin{aligned}
\#\{\mathcal{Q}_{\boldsymbol{\mu}}^\phi(\mathbb{F}_q)\} &= q^{n^2(g-1)}(q-1)\sum_{O}\frac{|O|}{|G^F|}\Lambda(O)\prod_{i=1}^k \mathcal{F}^{\mathfrak{g}}(1_{O_i})(O)\\
&= q^{n^2(g-1)}(q-1)\sum_{\omega\in\mathbf{T}_n}\mathcal{H}_\omega(0, \sqrt{q})\sum_{O}\prod_{i=1}^k \mathcal{F}^{\mathfrak{g}}(1_{O_i})(O)
\end{aligned}$$

where the second sum is over the adjoint orbits $O$ of $\mathfrak{g}^F$ of type $\omega$. The type of adjoint orbits is defined exactly as for conjugacy classes, see §4.1. We need the following lemma

**Lemma 6.2.3.** *Given $\omega \in \mathbf{T}_n$, we have*

$$\sum_{O}\prod_{i=1}^k \mathcal{F}^{\mathfrak{g}}(1_{O_i})(O) = \frac{q^{1+\sum_i d_i/2}}{q-1}\mathbf{H}_\omega^{\boldsymbol{\mu}_\dagger}(q)$$

*where the sum is over the adjoint orbits of type $\omega$, where $\boldsymbol{\mu}_\dagger$ is as in §6.1 and where $d_i = n^2 - \sum_j (\mu_j^i)^2$.*

*Proof.* We first remark that if $C$ is a semisimple adjoint orbit of $\mathfrak{g}^F$ of type $(1,1^{n_1})(1,1^{n_2})...(1,1^{n_r})$, then by Formula (2.6.5)

$$\mathcal{F}^{\mathfrak{g}}(1_C)=\epsilon_G\epsilon_L|W_L|^{-1}\sum_{w\in W_L}q^{d_L/2}\mathcal{R}^{\mathfrak{g}}_{\mathfrak{t}_w}(\mathcal{F}^{\mathfrak{t}_w}(1_\sigma^{T_w}))$$

where $L=\prod_{i=1}^r\mathrm{GL}_{n_i}(\overline{\mathbb{F}}_q)$ and where $\sigma\in C\cap L$.

If $\mathcal{X}$ is an irreducible character of type $(1,(n_1)^1)(1,(n_2)^1)...(1,(n_r)^1)$, by Formula (2.6.2) we have

$$\mathcal{X}=\epsilon_G\epsilon_L|W_L|^{-1}\sum_{w\in W_L}R^G_{T_w}(\theta^{T_w})$$

where $L=\prod_{i=1}^r\mathrm{GL}_{n_i}(\overline{\mathbb{F}}_q)$. Hence from the formulae (2.6.1) and (2.6.4) we see that the calculation of the values of $\mathcal{X}$ and $\mathcal{F}^{\mathfrak{g}}(1_C)$ is completely similar. We thus may follow the proof of Theorem 4.3.1(2) to compute $\sum_O\prod_{i=1}^k\mathcal{F}^{\mathfrak{g}}(1_C)(O)$. To do that we need to use the Lie algebra analogue of Proposition 4.2.1 which is as follows. Let $M$ be an $F$-stable Levi subgroup of $G$ of type $\omega\in\hat{\mathbf{T}}_n$ with Lie algebra $\mathfrak{m}$. We say that a linear character $\Theta: z(\mathfrak{m})^F\to\overline{\mathbb{Q}}_\ell$ is *generic* if its restriction to $z(\mathfrak{g})^F$ is trivial and if for any proper $F$-stable Levi subgroup $H$ containing $M$, its restriction to $z(\mathfrak{h})^F$ is non-trivial. Put

$$z(\mathfrak{m})_{\mathrm{reg}}:=\{x\in z(\mathfrak{m})|\,C_G(x)=M\}.$$

Then

$$\sum_{z\in z(\mathfrak{m})^F_{\mathrm{reg}}}\Theta(z)=qK^o_\omega$$

where $K^o_\omega$ is as in Proposition 4.2.1. The proof of this identity is completely similar to that of Proposition 4.2.1 except that here we are working with additive characters of $\mathbb{F}_q$ instead of multiplicative characters of $\mathbb{F}_q^\times$. This explains the coefficient $q$ instead of $q-1$. □

We thus have

$$\begin{aligned}\#\{Q^\phi_{\boldsymbol{\mu}}(\mathbb{F}_q)\}&=q^{n^2(g-1)}(q-1)\sum_{\omega\in\mathbf{T}_n}\mathcal{H}_\omega(0,\sqrt{q})\frac{q^{1+\sum_i d_i/2}}{q-1}\mathbf{H}^{\boldsymbol{\mu}^\dagger}_\omega(q)\\&=q^{d_\mu/2}\sum_{\omega\in\mathbf{T}_n}\mathcal{H}_\omega(0,\sqrt{q})\mathbf{H}^{\boldsymbol{\mu}^\dagger}_\omega(q).\end{aligned}$$

We may now proceed as in the proof of Theorem 6.1.1 to complete the proof of Theorem 6.2.2.

## 6.3 Quiver representations, Kac-Moody algebras and the character ring of $\mathrm{GL}_n(\mathbb{F}_q)$

Let $\Gamma$ be the comet-shaped quiver associated to $g$ and $\boldsymbol{\mu}$ as in §2.2 and let $\alpha$ be the dimension vector with dimension $\sum_{j=1}^l\mu^i_j$ at the $l$-th vertex on the $i$-th leg. Then

**Theorem 6.3.1.** *For $\boldsymbol{\mu}$ indivisible the two followings are equivalent:*

*(a)* $\left\langle\Lambda\otimes R_{\boldsymbol{\mu}},1\right\rangle\neq0$.

*(b) The quiver variety $Q_{\boldsymbol{\mu}}$ is non-empty.*

*For $g=0$ (a) or (b) hold if and only if $\alpha$ is a root of the Kac-Moody algebra $\mathcal{A}$ associated to $\Gamma$.*

*Proof.* The equivalence between (a) and (b) follows from the theorems 6.2.1 and 6.1.1. If $g=0$, then it is proved by Crawley-Boevey [2, §6] that $Q_{\boldsymbol{\mu}}$ is non-empty if and only if $\alpha$ is a root of $\mathcal{A}$. □

As mentioned in the introduction, the problem of the non-emptiness of $\mathcal{Q}_{\boldsymbol{\mu}}$ in the genus $g = 0$ case, which is part of the Deligne-Simpson problem, was first solved by Kostov [24][25]. The equivalence of (a) and (b) in Theorem 6.3.1 is formally similar to the connection between the Horn's problem (which asks for which partitions $\lambda, \mu, \nu$ does $H_\lambda + H_\mu + H_\nu = 0$ have solutions in Hermitian matrices) and the problem of the non-trivial appearance of the trivial representation in the tensor product $V_\lambda \otimes V_\mu \otimes V_\nu$ of the irreducible representations $V_\lambda, V_\mu, V_\nu$ of $\mathrm{GL}_n(\mathbb{C})$ [23].

We conclude with a naturally arising question: Can the identity $A_{\boldsymbol{\mu}}(q) = \left\langle \Lambda \otimes R_{\boldsymbol{\mu}}, 1 \right\rangle$ in §1.4 be strengthened by establishing an explicit bijection between the set of isomorphic classes of absolutely indecomposable representations of $\Gamma$ and a basis of $(V_\Lambda \otimes V_1 \otimes \ldots \otimes V_k)^{\mathrm{GL}_n(\mathbb{F}_q)}$ where $V_\Lambda := \left(\overline{\mathbb{Q}}_\ell[\mathfrak{gl}_n(\mathbb{F}_q)]\right)^{\otimes g}$ and $V_i$ is a representation of $\mathrm{GL}_n(\mathbb{F}_q)$ which affords the character $\mathcal{X}_i$?

# 7 Appendices

## 7.1 Appendix A

Fix integers $g \geq 0$, $k, n > 0$. We now construct a scheme whose points parametrize representations of the fundamental group of a $k$-punctured Riemann surface of genus $g$ into $\mathrm{GL}_n$ with prescribed images in conjugacy classes $C_1, \ldots, C_k$ at the punctures. We give the construction of this scheme in stages to alleviate the notation.

Fix $\boldsymbol{\mu} = (\mu^1, \mu^2, \ldots, \mu^k) \in \mathcal{P}_n{}^k$ and let $a^i_j$, for $i = 1, \ldots, k$; $j = 1, \ldots, r_i := l(\mu^i)$, be indeterminates. We should think of $a^i_1, \ldots, a^i_{r_i}$ as the distinct eigenvalues of $C_i$ each with multiplicity $\mu^i_j$; it will be in fact convenient to work with the multiset $\mathbf{A}_i := \{a^i_1, \ldots, a^i_1, a^i_2, \ldots, a^i_2, \ldots, a^i_{r_i}, \ldots, a^i_{r_i}\}$. To simplify we write $[\mathbf{A}] := \prod_{a \in \mathbf{A}} a$ for any multiset $\mathbf{A} \subseteq \mathbf{A}_i$.

Let

$$R_0 := \mathbb{Z}[a^i_j] / \left(1 - [\mathbf{A}_1] \cdots [\mathbf{A}_k]\right)$$

and consider the multiplicative set $S \subseteq R_0$ generated by (the classes of) $a^i_{j_1} - a^i_{j_2}$ for $j_1 \neq j_2$ and $1 - [\mathbf{A}'_1] \cdots [\mathbf{A}'_k]$ for $\mathbf{A}'_i \subseteq \mathbf{A}_i$ of the same cardinality $n'$ with $0 < n' < n$.

Since $R_0$ is reduced and $S$ does not contain 0 the localization

$$R := S^{-1} R_0$$

is not trivial ($R$ is a ring with 1). We refer to it as the *ring of generic eigenvalues of type* $\boldsymbol{\mu}$.

In the special case where $k = 1$ and $\mu = (n)$ we have

$$R_0 = \mathbb{Z}[a]/(1 - a^n)$$

and $S \subseteq R_0$ is the multiplicative set generated by $(1 - a)^{n'}$ for $1 \leq n' < n$.

**Lemma 7.1.1.** *For $k = 1$ and $\mu = (n)$ the ring $R = S^{-1} R_0$ is isomorphic to $\mathbb{Z}[\frac{1}{n}, \zeta_n]$, where $\zeta_n$ is a primitive $n$-th root of unity.*

*Proof.* The natural map $\psi : R_0 \to R = S^{-1} R_0$ has kernel the ideal generated by $(1 - a^n)/(1 - a^{n'})$ for $1 \leq n' < n$. This means that $\psi$ factors through $\mathbb{Z}[\zeta_n] \hookrightarrow R$ with $\psi(a) = \zeta_n$. Since

$$\prod_{i=1}^{n-1} (1 - \zeta_n^i) = n$$

and each factor is in the image of $S$ it follows that $\frac{1}{n} \in R$. Hence $\mathbb{Z}[\frac{1}{n}, \zeta_n] \hookrightarrow R$.

By the same token, the map $\phi : R_0 \to \mathbb{Z}[\frac{1}{n}, \zeta_n]$ sending $a$ to $\zeta_n$ takes $1 - a^{n'}$ to a unit. Hence by the universal property of $R$ there is a unique extension $\phi : R \to \mathbb{Z}[\frac{1}{n}, \zeta_n]$. This completes the proof. ◻

In general, we have a map $\mathbb{Z}[a]/(1-a^d) \hookrightarrow R_0$, where $d := \gcd(\mu^i_j)$, defined by sending $a$ to $\prod_{i,j}(a^i_j)^{\mu^i_j/d}$. By the lemma we get $\mathbb{Z}[\frac{1}{d}, \zeta_d] \hookrightarrow R$.

Recall the definitions from §2.1. Note that up to a possible reordering of eigenvalues of equal multiplicity a map $\phi : R \to \mathbb{K}$ uniquely determines a $k$-tuple of semisimple generic conjugacy classes $(C^\phi_1, C^\phi_2, \ldots, C^\phi_k)$ of type $\boldsymbol{\mu}$ in $\mathrm{GL}_n(\mathbb{K})$ satisfying (2.1.2) and conversely ($C^\phi_i$ has eigenvalues $\phi(a^i_j)$ of multiplicities $\mu^i_j$).

Consider the algebra $\mathcal{A}_0$ over $R$ of polynomials in $n^2(2g+k)$ variables, corresponding to the entries of $n \times n$ matrices $A_1, \ldots, A_g; B_1, \ldots, B_g; X_1, \ldots, X_k$, with

$$\det A_1, \ldots, \det A_k; \quad \det B_1, \ldots, \det B_k; \quad \det X_1, \ldots, \det X_k$$

inverted. Let $I_n$ be the identity matrix and for elements $A, B$ of a group put $(A, B) := ABA^{-1}B^{-1}$.

Define $\mathcal{I}_0 \subset \mathcal{A}_0$ to be the radical of the ideal generated by the entries of

$$(A_1, B_1) \cdots (A_g, B_g) X_1 \cdots X_k - I_n, \qquad (X_i - a^i_1 I_n) \cdots (X_i - a^i_{r_i} I_n), \quad i = 1, \ldots, k$$

and the coefficients of the polynomial

$$\det(tI_n - X_i) - \prod_{j=1}^{r_i} (t - a^i_j)^{\mu^i_j}$$

in an auxiliary variable $t$. Finally, let $\mathcal{A} := \mathcal{A}_0/\mathcal{I}_0$ and $\mathcal{U}_{\boldsymbol{\mu}} := \mathrm{Spec}(\mathcal{A})$.

Let $\phi : R \to K$ be a map to a field $K$ and let $\mathcal{U}^\phi_{\boldsymbol{\mu}}$ be the corresponding base change of $\mathcal{U}_{\boldsymbol{\mu}}$ to $K$. A $K$-point of $\mathcal{U}^\phi_{\boldsymbol{\mu}}$ is a solution in $\mathrm{GL}_n(K)$ to

$$(A_1, B_1) \cdots (A_g, B_g) X_1 \cdots X_k = I_n, \qquad X_i \in C^\phi_i,$$

where, as before, $C^\phi_i$ is the semisimple conjugacy class in $\mathrm{GL}_n(K)$ with eigenvalues $\phi(a^i_1), \ldots, \phi(a^i_{r_i})$ of multiplicities $\mu^i_1, \ldots, \mu^i_{r_i}$.

Hence, if $\Sigma_g$ is a compact Riemann surface of genus $g$ with punctures $S = \{s_1, \ldots, s_k\} \subseteq \Sigma_g$ then $\mathcal{U}^\phi_{\boldsymbol{\mu}}(K)$ can be identified with the set

$$\{\rho \in \mathrm{Hom}\left(\pi_1(\Sigma_g \setminus S), \mathrm{GL}_n(K)\right) \mid \rho(\gamma_i) \in C^\phi_i\},$$

(for some choice of base point, which we omit from the notation). Here we use the standard presentation

$$\pi_1(\Sigma_g \setminus S) = \langle \alpha_1 \ldots, \alpha_g; \beta_1 \ldots, \beta_g; \gamma_1 \ldots, \gamma_g \mid (\alpha_1, \beta_1) \cdots (\alpha_g, \beta_g) \gamma_1 \cdots \gamma_k = 1 \rangle$$

($\gamma_i$ is the class of a simple loop around $s_i$ with orientation compatible with that of $\Sigma_g$).

*Remark* 7.1.2. A completely analogous construction works for the quiver case in the case that $\boldsymbol{\mu}$ is indivisible yielding an affine scheme $\mathcal{V}_{\boldsymbol{\mu}}$ with similar properties. For example, in the definition of $R_0$ and $R$ we replace the product of elements in a multiset by their sum to guarantee genericity (see 2.2.1). The primes $p \in \mathbb{Z}$ that become invertible in $R$ are those that are smaller than $\min_i \max_j \mu^j_i$ (compare with (2.2.1)).

## 7.2 Appendix B

Here we prove a version of the smooth-proper base change theorem. A closely related result was obtained by Nakajima [3, Appendix].

**Theorem 7.2.1.** *Let $X$ be a non-singular complex algebraic variety and $f : X \to \mathbb{C}$ a smooth morphism, i.e. a surjective submersion. Let $\mathbb{C}^\times$ act on $X$ covering the standard action on $\mathbb{C}$ such that the fixed point set $X^{\mathbb{C}^\times}$ is complete and for all $x \in X$ the $\lim_{\lambda \to 0} \lambda x$ exists. Then the fibers have isomorphic cohomology supporting pure mixed Hodge structures.*

*Proof.* The proof is similar to that of [16, Lemma 6.1], we give the details to be self-contained. Let $\mathbb{C}^\times$ act on $\mathbb{C}^2$ by $\lambda(z,w) = (\lambda z, w)$. Then $\mathbb{C}^2 \to \mathbb{C}$ given by $(z,w) \mapsto zw$ is $\mathbb{C}^\times$-equivariant with the standard action on $\mathbb{C}$. Let now $X'$ denote the base change of $X$ via this map, in other words $X' = \{(x,z,w) \in X \times \mathbb{C}^2 | f(x) = zw\}$. $X'$ then inherits the $\mathbb{C}^\times$ action given by $\lambda(x,z,w) = (\lambda x, \lambda z, w)$. Then $f$ induces the map $f' : X' \to \mathbb{C}$ by $f(x,z,w) = w$ which is equivariant with respect to the trivial action on the base. By [34, Theorem 11.2] the set $U \subset X'$ of points $u \in X'$ such that $\lim_{\lambda\to\infty} \lambda u$ does not exist is open and there exists a geometric quotient $\overline{X} := U//\mathbb{C}^\times$ which is proper over $\mathbb{C}$ via the induced map $\overline{f} : \overline{X} \to \mathbb{C}$. Indeed it is a completion of $X$ over $\mathbb{C}$ as $X \subset \overline{X}$ naturally by the embedding $x \mapsto \mathbb{C}^\times(x, 1, f(x))$.

We now show that $\overline{f}$ is topologically trivial. It is not entirely straightforward, as $\overline{X}$ is only an orbifold, because the action of $\mathbb{C}^\times$ on $U$ may not be free, there could be points with finite stablizers. However the multiplicative group $\mathbb{R}_+^\times$ of positive real numbers acts on $U$ as a subgroup of $\mathbb{C}^\times$. Therefore the action of $\mathbb{R}^\times$ on $U$ is free. It is properly discontinuous because the action of $\mathbb{C}^\times$ on $U$ is properly discontinuous as $U \to \overline{X}$ is a geometric quotient. The quotient space $U/\mathbb{R}_+^\times$ is therefore a smooth manifold and the total space of a principal $\mathbb{T} := \mathrm{U}(1)$ orbi-bundle over the orbifold $\overline{X}$, which is proper over $\mathbb{C}$. Hence the induced map $f_+ : U/\mathbb{R}_+^\times \to \mathbb{C}$ is a proper submersion. Thus by choosing a $\mathbb{T}$-invariant Riemannian metric on $U/\mathbb{R}_+^\times$ and flowing perpendicular to the projection, we find a $\mathbb{T}$-equivariant trivialization of $f_+$ in the analytic topology. Dividing out by the $\mathbb{T}$ action yields a trivialization of $\overline{f}$ in the analytic topology. Consequently the restriction $H^*(\overline{X}) \to H^*(\overline{X}_w)$ to the cohomology of any fibre of $\overline{f}$ is an isomorphism.

Note that $Z := \overline{X} \setminus X = \{\mathbb{C}^\times(x,0,w) | \lim_{\lambda\to\infty} \lambda x \text{ exists }\}$ is trivial over $\mathbb{C}$, therefore $H^*(Z) \to H^*(Z_w)$ is an isomorphism. Applying the Five Lemma to the long exact sequences of the pairs $(\overline{X}, Z)$ and $(\overline{X}_w, Z_w)$ we get that $H^*(\overline{X}, Z) \cong H^*(\overline{X}_w, Z_w) \cong H^*_{cpt}(X_w)$. Thus any two fibres of $f$ have isomorphic cohomology, in particular $H^*_{cpt}(X_w) \cong H^*_{cpt}(X_0)$ for all $w \in \mathbb{C}$. As $\overline{X}_0$ is a proper orbifold (in particular a rational homology manifold) [5, 8.2.4] implies that its cohomology has pure mixed Hodge structure. Finally, by standard Morse theory arguments $H^*(\overline{X}_0) \to H^*(X_0)$ is surjective thus $H^*(X_0)$ also has pure mixed Hodge structure. The proof is complete. □
